ÖZET

VERİ ZARFLAMA ANALİZİ İLE HASTANE VERİMLİLİĞİNİN ÖLÇÜMÜ VE DEĞERLENDİRİLMESİ

Günümüzde sağlık sektörü etkinliğinin arttırılması önem kazanmıştır. Sağlık harcamalarının en büyük payına sahip olan hastanelerin etkin olarak idare edilmesi hem kalitenin arttırılması hem de bütçe giderlerinin azaltılması açısından önemlidir. Sağlık sektörüne özel hastanelerin de dahil olması ile birlikte rekabet artmış ve devlet hastanelerinin yeniden düzenlenmesi kaçınılmaz olmuştur. Sağlık sektörünün gelişimi için devlet tarafından oluşturulan “Sağlıkta Dönüşüm Programı” ile etkin, ulaşılabilir ve yüksek kalitede sağlık hizmeti hedeflenmiştir.

Bu çalışmada hastane verimliliği açısından kendini kanıtlamış bir yöntem olan veri zarflama analizi kullanılmıştır. Türkiye'nin çeşitli ilçelerinde yer alan 444 devlet hastanesi incelenmiştir. Çalışmada “output-oriented” model kullanılmıştır ve hastanelerin “RTS regions” sınıflandırılması yapılmıştır.

Ortaya çıkan sonuçlar incelendiğinde etkinsizliğin genel olarak ilçelerin aşırı göç almasından ya da göç vermesinden dolayı yaşanan dinamik yapı karşısında hastanelerin uyum sağlayamamasından kaynaklandığı görülmüştür.

Hastanelerin daha etkin hale getirilmesi için önerimiz; temel olarak hastanelerin ulaşılabilirliği göz önüne alınarak, göç kaybeden ilçelerde yer alan diğer bir ifade ile hasta bulamadığı için etkinsiz olan hastanelerin birleştirilmesi, aşırı göç alan ilçelerde yer alan ve hastane kaynakları hasta karşısında yetersiz kalan hastanelerin bölünme yoluna giderek, ihtiyaç olunan bölgede büyümeye yoluna gitmesidir.

ABSTRACT

MEASUREMENT AND EVALUATION OF HOSPITAL EFFICIENCY BY DATA ENVELOPMENT ANALYSIS

Nowadays, boosting the efficiency of health sector has gained importance. Efficient management of hospitals that have the biggest share in health expenditures is significant both for the increase in quality and the decrease in budget costs. With the entrance of private hospitals into health sector, competition has increased, making the regulation of public hospitals inevitable. Efficient, accessible and high quality health service is aimed with “Transformation of Health Program” launched by the government for the development of health sector.

Data envelopment analysis method, a proven method for hospital efficiency, is used for this thesis. 444 public hospitals in various cities of Turkey have been analyzed. In the thesis, “output-oriented” model is used and hospitals have been classified as “RTS regions”.

Analyzing the results, it has been observed that the inefficiency stems from hospitals’ inability to adapt to the dynamic structure arising from extreme immigration figures to and from districts.

Our suggestion for boosting the efficiency of hospitals is that considering the accessibility of hospitals; the ones in emigrant districts in other words the hospitals that are inefficient due to lack of patients are combined and the ones in immigration receiving districts where hospital resources remain incapable be enlarged in needed regions.

CHAPTER I

INTRODUCTION AND PURPOSE

I.1 INTRODUCTION

Turkish public health system is controlled by the Ministry of Health. The Ministry is vested with the authority to provide medical care and preventive health services, train health personnel, provide pre-service and in-service training, establish and operate health institutions and authorize the establishment and oversee medical institutions by other public and private organizations. The Ministry also regulates prices of medical drugs and controls drug production and operations of pharmacies (TUIK, 2010). The Ministry of Health was established in 1920 and made legal arrangements in many fields between the years 1920-1938. The priority aims of these arrangements were;

- Solving the post-war problems,
- Supporting health personnel in quality and quantity,
- Establish the structure starting from center to village,
- Spreading preventive health services (The Ministry of Health, 2003)

41% of the resources transferred to health sector are subsidized with general tax and fund revenues. The reason of these taxes and funds collected separately from health insurance and retirement fund contributions is not supporting curative health sector; these are the real investments for the development of the country. The expenditures on employees with low labor productivity and curative medical applications constitute the major part of the resources transferred to the sector. Thus, public revenues are squandered. (Savas, 2003)

Increased health expenditure caused argument about health system in Turkey. For more effective health system, new health program started, named as “Health Transformation Program” According to the Ministry of Health report, “Health Transformation Program will deliver the health services in a qualified, effective, sustainable and equal way and will be a system that will assume an increase in income level based on the performance of health performance of health professionals.” And they conclude their report with “All our need is people who are determined and hardworking” (The Ministry of Health, 2003).

Growing health expenditures, increased quality and competition in the health sector put pressure on government hospitals to use their resources more efficiently if they want to compete with the private hospitals (Temur, 2008).

In this thesis study, we aim to show efficiency of Turkey’s public hospitals by using data envelopment analysis techniques. Data envelopment analysis is a very popular and useful technique to evaluate hospitals’ efficiency.

CHAPTER II

DATA ENVELOPMENT ANALYSIS

Recent years have seen a great variety of applications of DEA (Data Envelopment Analysis) for use in evaluating the performances of many different kinds of entities engaged in many different activities in many different contexts in many different countries. One reason is that DEA has opened up possibilities for use in cases which have been resistant to other approaches because of the complex (often unknown) nature of the relations between the multiple inputs and multiple outputs involved in many of these activities (which are often reported in non-commeasurable units) (Cooper, 1999).

DEA is a mathematical optimization model used to measure the relative efficiency of organizations or parts of organizations (referred to as ‘decision-making units’) that have similar attributes and share the same goals and objectives (for example, dairy farms producing milk). This method has been used to evaluate the performance of many different types of organizations performing a variety of activities, including both profit- and nonprofit-making organizations. (Rouse, 2010). DEA has also been used to supply new insights into activities (and entities) that have previously been evaluated by other methods (Cooper, 1999).

According to DEA method, each unit is regarded as a decision-making unit (DMU), and all of the DMUs constitute the groups being evaluated. Then the input output efficiency is analyzed and the production frontier is determined by calculating the weights of the input and output indicator of each DMU. In fact, the production frontier is the effective part of envelopment, which is constructed by the observed input and output data points of each DMU. That is why the method is called data

envelopment analysis. Whether a certain DMU is efficient or not is determined by the distance between its data point and the production frontier. If the data point lies on the production frontier, that means the DMU which it represents is fully technically efficient. The effective DMU can be considered in the ideal status already, in the corresponding scale of input it has been achieved on the largest output. (Tang et. al., 2008)

DEA, the evaluation value is measured by comparing an objective DMU with the best practice frontier which is called “efficiency frontier”. Figure III.2 assumes that there are four DMUs, i.e. soccer teams (A, B, C and D) which have a single input (the number of back passes) and a single output (the number of offensive passes). The larger the ratio of output to input, the more efficient the activity of DMU is. (Aoki, 2009)

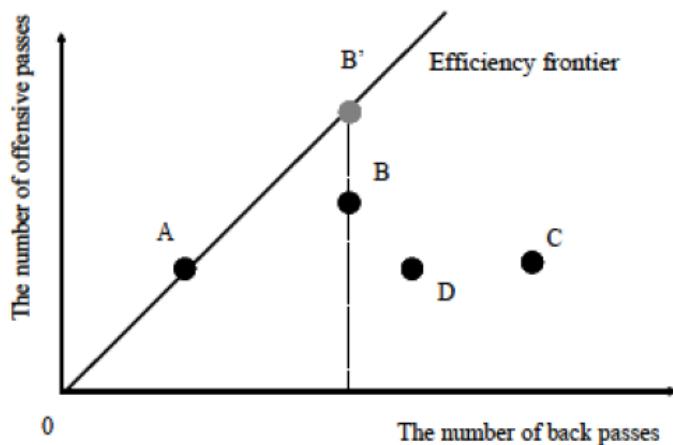

Figure II.1: Efficiency frontier and efficiency value

Another example stated in figure III.3, there are six DMUs (A~F) which have one input and two outputs are evaluated. Each axis indicates outputs divided by input. Therefore, DMU which is far from origin is more efficient. Four DMU (A~D) are the state of efficient since they are located on efficiency frontier. Territory enclosed with origin and efficiency frontier is called possible production set. Then all evaluated DMUs are in this territory. And DMUs which achieve maximum output can be state of efficiency. (Naito et. al., 2009)

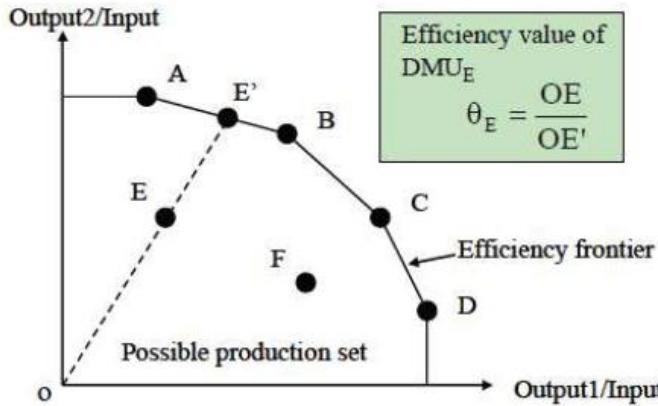

Figure II.2: Efficiency frontier and efficiency value of DMU

If the units produce multiple outputs using various input factors, the efficiency of DMU_j is defined as the ratio between a weighted sum of the outputs and a weighted sum of the inputs. Denote by H = {1, 2, . . . , s} the set of production factors and by K = {1, 2, . . . , m} the corresponding set of outputs. If x_{ij}, i ∈ H, denotes the quantity of input i used by DMU_j and y_{rij}, r ∈ K, the quantity of output obtained, the efficiency of DMU_j is defined as;

$$\theta_j = \frac{u_1 y_{1j} + u_2 y_{2j} + \dots + u_m y_{mj}}{v_1 x_{1j} + v_2 x_{2j} + \dots + v_s x_{sj}} = \frac{\sum_{r \in K} u_r y_{rj}}{\sum_{i \in H} v_i x_{ij}}$$

for weights u₁, u₂, . . . , u_m associated with the outputs and v₁, v₂, . . . , v_s assigned to the inputs. (Vercellis, 2009)

III.1.1 CCR Model

The model developed in Charnes, Cooper and Rhodes (1978), known as the CCR model, imposes three restrictions on the frontier technology: Constant returns to scale, convexity of the set of feasible input-output combinations; and strong disposability of inputs and outputs (Zamorona, 2004). There is production frontier of CCR model at Figure II.3.

Source: (Cooper, 1999)

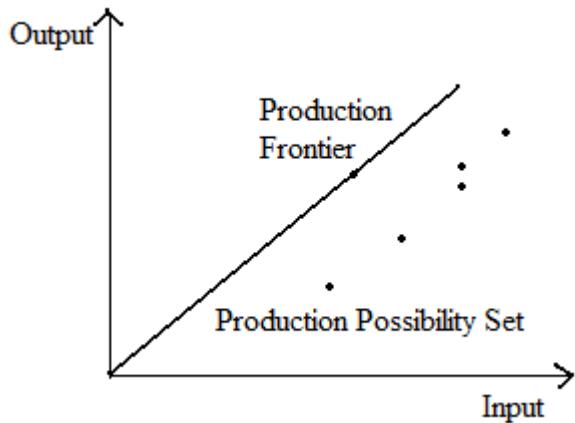

Figure II.3: Production Frontier of CCR Model

III.1.2 BCC Model

BCC model is introduced by Banker-Charnes-Cooper in 1984 (Banker et al, 2003). The BCC model's production frontiers spanned by the convex of the existing DMUs. (Cooper, 1999). According to another statement BCC model's sum of λ equals 1. (Kecek, 2010). There is production frontier of BCC model at Figure II.4.

Source: (Cooper, 1999)

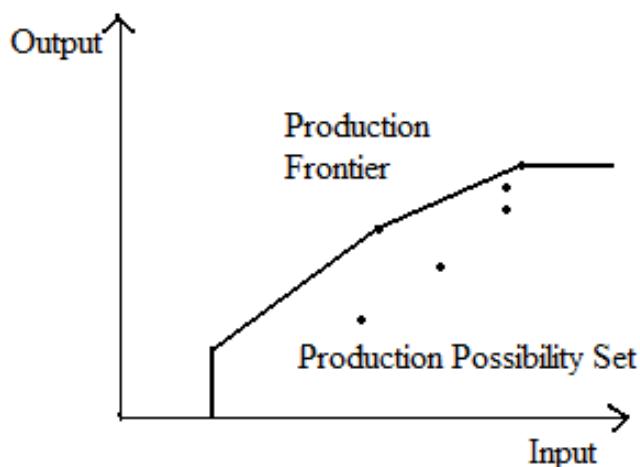

Figure II.4: Production Frontier of BCC Model

III.1.3 Returns to Scale Region

Returns to scale called as “elasticity” in economics and measures the relative change in output compared to the relative change in input (Cooper, 1999).

RTS classifications will be assigned in six regions. Region I refers IRS, region II refers CRS, region III refers DRS, region IV refers IRS at input-oriented model and CRS at output-oriented model, region V refers CRS at input-oriented model and DRS at output-oriented model, region VI refers IRS at input-oriented model and DRS at output-oriented model (Zhu, 2009).

CHAPTER III

LITERATURE

III.1 STUDIES ABOUT HOSPITALS' EFFICIENCY

Data envelopment analysis technique is very useful to evaluate firms' efficiency and very common to evaluate hospitals' efficiency. There are various studies about Hospital efficiency used by DEA.

Linna (1998) used DEA to calculate efficiency scores of Finnish Hospitals in his paper. Economic recession and the Government's budget caused pressure on hospitals in Finland to contain costs. He used DEA because productive efficiency needed to enhance. In conclusion, 3–5% annual average increase in productivity, half of which was due to improvement in cost efficiency and half due to technological change.

Al-Shammari (1999) attempted to apply Data Envelopment Analysis (DEA) to the measurement of productive efficiency of hospitals in the context of a developing country. He illustrated to assess the productive efficiency of the Ministry of Health's hospitals in Jordan. As a result DEA provided the first efficiency and productivity database of public hospitals in Jordan. He emphasis that, based upon DEA results, senior MOH's officials and policy-makers may need to mobilize some of the resources from one hospital to another.

Staat et. al. (2000), used DEA to evaluate German Health Sector efficiency. To deliver benchmarking result, a method was chosen. They discussed in their paper that the deficiencies of the chosen method could be overcome by using DEA. In their study, they showed that significant productivity differences exist between very similar hospitals. And also, they pointed out most inefficient hospitals could half their cost by applying an efficient technology.

Güles et. al. (2007) analyzed 50 largest hospitals owned by the Social Security Organization in Turkey by DEA in their study. Only 14 of them were found efficient. The authors suggest administrative and organizational restructuring of the 36 inefficient hospitals which have an average efficiency rate of 74%.

Gonçalves et. al. (2007) used DEA to measure hospitals according to the performance of decision-making units in relation to the variables studied for each hospital, in the year 2000. Clinical medical admissions in hospitals within the public system in Brazilian state capitals and Federal District (mortality rate, mean length of stay, mean cost of stay and disease profile) were analyzed. As a result, among the 27 state capitals, four of them were found to be 100% efficient, seven of them were found to be between 85 and 100%, ten of them were found to be between 70 and 85% and ten of them were found to be efficient less than 70%.

Zweifel et. al. (2009) introduce health efficiency by showing economic aspect in their book. They mention about data envelopment techniques to measure hospital efficiency. They pointed out to measure hospitals' efficient qualitative data is also important besides quantitative data. They use alternative techniques to understand the health economics.

Jandaghi et. al. (2010), evaluate and compare efficiency of Qom/Iran private and public hospitals in their study. They used Data Envelopment Analysis (DEA) in which rate of output is evaluated by input and effective and non-effective units are determined. The number of physicians, the number of nurses, the number of medical staff, the number of official staff and the amount of annual cost are their application's inputs. Clinical visits, emergency visits, and occupied cot/beds are their application's outputs. They analyzed 8 hospitals, using two methods: CRS & VRS (Constant Return to Scale & Variable Return to Scale). In conclusion, 3 hospitals among them were found to be non-effective.

Najadat et. al. (2011) used different algorithms and methods related to DEA to evaluate 28 public hospitals in Jordan. They consider the number of physicians, number of pharmacists, number of nurses, other hospital employees, number of beds, labs as inputs and number of inpatients, number of patients treated or outpatients, outpatients' visits, number of surgical operations, emergency room visits and length of stay for inpatients as outputs. As a result 8 of them were found to be efficient using all different methods or algorithms

Karahan et. al. (2011) used DEA techniques to evaluate performance of hospitals in Turkey. They mention the management of Turkish hospitals by showing hospitals' organizational structure and problems in their book. They conclude that, hospitals are organizations quality of which must be improved day by day. Hospitals' performances are needed to be measured by numeric techniques to improve their quality. Authors pointed out those DEA techniques are very useful for evaluating hospital's performance.

Hollingsworth (2008), review 317 published paper about frontier efficiency measurement and dwell upon conceptualizations of efficiency at his paper. According to his paper, %50 of the paper was applied on hospitals and DEA techniques were used %47 of the papers. In conclusion, he point out some criteria for assessing the use and usefulness of efficiency studies. He suggest that, sample sizes increase, and statistical techniques evolve can help in well-conducted studies in this

area. And he pointed out check list which could use for efficiency measurement studies;

1. Is the question well defined, and answerable?
2. Is a comprehensive description of the sample given?
3. Are the quality and quantity output data clear and comprehensive?
4. Are all the relevant inputs and outputs included?
5. Are inputs and outputs measured accurately in appropriate units?
6. Were inputs and outputs (or objectives) valued (or weighted) correctly?
7. Were analyses over time undertaken?
8. Do techniques add incremental value?
9. Was allowance made for uncertainty?
10. Did the presentation and discussion of study results include all issues of concern to users?

O'Neill et. al. (2007), review 79 studies published from 1984–2004 that represent 12 countries at their paper. They evaluate the papers in 4 categorize. 37 studies which used standard DEA and DEA with congestion, multifactor efficiency, multi-objective optimization, scale efficiency, and translog cost functions model defined as group 1. 23 studies used DEA to measure changes in technical efficiency over time. 7 of them used DEA in combination with the Malmquist index. They pointed out that DEA in combination with the Malmquist index is advantageous to measure technological change over time as well as changes in the efficiency of individual facilities, e.g., hospitals. 12 studies located in group 3. These studies used allocate DEA, stochastic DEA, DEA in combination with SFA. They pointed out stochastic DEA offered the advantage of separating statistical noise from inefficiency. 7 studies located in group 4. 5 of them used DEA with another technique such as SFA. They pointed out these studies required a more complex design. They classified the inputs as beds, clinical staff, and non-clinical staff, working hours, services offered, costs, typical and specific input categories. In conclusion, they found significant differences between Europe and the US about study characteristic;

1. Fifty-two percent of European studies incorporated allocate efficiency (12% of US studies did). Sixty percent of European studies used panel data (25%

of the US studies did). 53% of the European studies used panel data and the Malmquist index approach (%7 US studies did).

2. European studies were significantly more likely to use panel data than were US studies. Panel data offer several advantages over cross-sectional data, especially for measuring the impact of changes in hospital reimbursement.
3. Due to a larger American population, US studies had significantly more hospitals and hospitalsper-category than did the European studies.

CHAPTER IV

APPLICATION

IV.1. DEFINITIONS

Hospital: Institutions, which provide in-patient or out-patient medical care, in compliance with the medical and sanitary conditions required.

SII (Social Insurance Institution) Hospitals: The SII hospitals were devolved to the Ministry of Health in 2005. There were 120 SII hospitals with 28 979 beds in 2002. Total 43 561 287 visits were made to these hospitals and 1 363 191 patients were hospitalized. 553 839 surgical operations were performed; 265 252 of them were minor surgeries while 168 604 were intermediate and 119 983 were major surgeries. The number of days stayed in hospital was 7 736 937 and 19 360 patients died. In 2005, 146 hospitals with 35 059 hospital beds were devolved to the MoH.

Bed Capacity: Shows number of beds, in which a patient lies down for more than 24 hours for the purpose of care and treatment, and which is located in a patient room or patient wards/units, where patients are provided with continuous medical care services

General Practitioners: The person who has completed 6 years of higher education in medicine after graduating from high school.

Specialists: The person who have had a further period of residency training in a special field/branch of medicine, are called specialists

Health Personnel: Health Personnel include technicians, who hold high school degree and associate degree in the following branches: Emergency care, health, anesthesia,

environmental health, dental prosthesis, laboratory, orthopedics, x-ray, dental care, physical therapy, heart-lung-pump, pathological anatomy, audiometry, prosthesis and population health.

Midwife, nurse: Health personnel with a 4-year bachelor degree after graduation from high school. Those, who graduate from midwifery departments in vocational health high schools, are called midwives while others, who graduated from nursing departments in vocational health high schools, are called nurses. (TUIK, 2010).

Surgeries Type I: Cardiac transplantation, craniectomy –pneumonectomy to receiver with heart -lung transplantation, kidney transplantation, small intestine transplantation, free flap containing three different tissues, hematopoietic cell transfer, allogeneic, aorta replacement with aortic root expansion, mitral valve reconstruction, hypoplastic left heart syndrome repair, hepatectomy total, Pharyngolaryngectomy, mediasten cyst/tumor excision, by -pass graft composite (graft + vein) etc.

Surgeries Type II: Excision of malign skin tumors, open rhinoplasty with total septal reconstruction, laryngectomy total, mandibular or maxillary reconstruction, bone graft with cranial encephalocele surgeries, other tumor excision, intratorasic, extrapulmonary etc.

Surgeries Type III: Muscular flab, cleft palate repair -incomplete, lapa temporomandibular joint endoscopy, surgical rostomy, Caldwell -Luc operation, (bilateral), rhinoplasty, uncomplicated, non -graft endoscopic concha reduction, larynx papilloma etc.

Surgeries Type IV: Foreign body extraction from nose – surgery, only pacemaker or AICD installation/placement, open biopsy for soft tissue tumor inside pelvis, external rhino -surgery, internal rhino -conca electrocoterization, rhinophima excision and forehead flab secondary séance etc.

Surgeries Type V: Long leg plaster (above knee), cervical polyp excision, gastroscopic polypectomy, conjonctiva cover, bumm abortion, cervical biopsy, unilateral testicular venography, dialysis fistulograph, circumcision, colposcopy, pericariodsynthesis, parafimozis reduction etc. (The Ministry of Health, 2008)

IV.2. DATA AND ANALYSIS RESULT

In this study, 444 public hospitals located in Turkey have been analyzed. New generation DEA software, Max DEA 5.2 is used. Inputs and outputs are showed on Table X and Table Y.

Table IV.1: Inputs of the thesis study and number distribution according to bed capacity

Bed Capacity	Number of Hospitals	Specialists	General Practitioners	Midwife/ Nurse	Health Personnel	Other Personnel
0-50	187	7	7	49	49	6
51-100	92	17	9	83	83	16
101-200	66	36	13	139	139	22
201-350	59	65	18	249	249	37
351+	40	110	28	475	475	67

Source: Prepared by author

Table IV.2: Output of the thesis study and number distribution according to bed capacity

Bed Capacity	Outpatients	Surgeries Type I	Surgeries Type II	Surgeries Type III	Surgeries Type IV	Surgeries Type V
0-50	105424	19	64	149	122	54
51-100	243612	27	309	729	580	562
101-200	401024	147	857	1666	1440	1384
201-350	516459	263	1543	2480	2451	3348
351+	693134	411	2277	3725	4341	9877

Source: Prepared by author

Envelopment model is used to analyze the data. We characterized DMUs' RTS classifications and we found DMUs' located region (see Table IV.3). The analysis result shows that only 9% of hospitals (42 hospitals) are efficient and located in region II. 46% of hospitals (203 hospitals) are located in Region I. These are inefficient and their input and output RTS classifications are "increasing returns to scale". 15% of hospitals (64 hospitals) are located in Region III. These are inefficient and their input and output RTS classifications are "decreasing returns to scale". 1 hospital's input-oriented RTS classification is "increasing returns to scale" and output-oriented RTS classification is "constant returns to scale". It is inefficient and located in Region IV.

Table IV.3: Number of DMU and average bed capacity according to region

Region	Number of DMU	Average bed capacity
Region I (IRS)	203	91
Region II (CRS)	42	174
Region III (DRS)	65	285
Region IV	1	-
Region V	-	-
Region VI	133	106

Source: Prepared by author

There is no hospital located in Region V. 30% of hospitals are located in Region VI and their input-oriented RTS classification is "increasing returns to scale" and output-oriented RTS classification is "decreasing returns to scale" (see at Table IV.3 and figure IV.1).

Source: Prepared by author

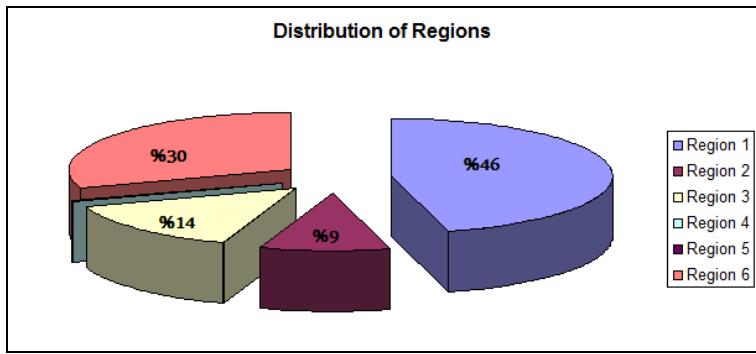

Figure IV.1: Distribution of Regions

When papers were analyzed it seems that especially, USA located hospitals performance measured by using input oriented DEA model. In literature it is expressed that hospital managers and policy-makers generally have more control over their inputs than their outputs, hence input-oriented DEA model is more suitable for our study. (O'Neill et. al., 2008). However, we consider input and output oriented analysis results and we show RTS regions of DMUs (see Table IV.4). According to OECD 2008 report Turkey has low bed ratio, low bed occupancy and short average length of stay in hospital when considered OECD's average value (OECD, 2008). Papers which study on Turkey hospital efficient find “input waste” on hospitals (Bilsel, 2010). In light of the foregoing, to improve Turkey hospital efficient we should increase the hospitals output size (Davutyan, 2011).

Table IV.4: Population Trend According to Region

		Localities with Increasing Population			Localities with Decreasing Population		
Region	Number of DMU	Number of Hospitals	% of Hospitals	Average Population Gain	Number of Hospitals	% of Hospitals	Average Population Lost
Region I (IRS)	203	119	59%	92%	84	41%	-21%
Region II (CRS)	42	33	79%	187%	9	21%	-31%
Region III (DRS)	65	53	82%	160%	12	18%	-22%
Region IV	1	0	-	-	1	100%	-36%
Region V	-	0	-	-	0	-	-
Region VI	133	72	54%	203%	61	46%	-20%

Source: Prepared by author

Table IV.5 shows us population trend's characters according to output-oriented RTS classification. Output oriented analysis results show us 41% of hospitals are IRS and these hospitals located cities have lost population average 21%. On the other hand, 63% of DRS hospitals located in cities which have had rapidly increase population, average 187% increases for 10 years.

Table IV.5: Population Trend According to Output-Oriented RTS Classification

Output-oriented								
		Localities with Increasing Population			Localities with Decreasing Population			
	Sum	Number of Hospitals	% of Hospitals"	Average Population Gain	Number of Hospitals	% of Hospitals	Average Population Lost	
Increasing (IRS)	203	119	59%	92%	84	41%	-21%	
Decreasing (DRS)	198	125	63%	187%	73	37%	-21%	
Constant (CRS)	43	33	77%	138%	10	23%	-31%	

Source: Prepared by author

According to output-oriented analysis result, 50% of hospitals located in cities with decreasing population classified as IRS.(see Table IV.6) Ratio of hospitals according to population is 6%. These hospitals efficient could be improved by associated. Thus their outputs will increase.

Other result of the output-oriented analysis, 45% of hospitals located in cities with increasing population classified as DRS (see Table IV.6). Ratio of hospitals according to population is 45%. These hospitals efficient could be improved by diminished. Thus their outputs will decrease.

Table IV.6: Output-Oriented RTS Classification according to Population Trend

Output-oriented						
	Sum	Increasing (IRS)		Decreasing (DRS)		Constant (CRS)
Localities with Increasing Population	277	119	43%	125	45%	33
Localities with Decreasing Population	167	84	50%	73	44%	10
						12%
						6%

Source: Prepared by author

When surgery types are analyzed, it seems that there is positive relation between surgery units and percentage region II. This means, more surgeries cause more efficient hospitals (see Table IV.7).

Table IV.7: Surgery Types' Region According to Surgery Units

Surgery Type I	Bed Capacity	Bed Capacity Utilization Rate	Sum of Surgery Units	Sum of Population	% of Surgeries/Population
Region I (IRS)	18.560	79%	14.713	15.141.267	0,10%
Region II (CRS)	7.301	81%	5.917	9.335.560	0,06%
Region III (DRS)	18.238	75%	13.745	15.243.732	0,09%
Region IV	25	0%	0	21.054	0,00%
Region V	0	0%	0	0	0,00%

CHAPTER V

CONCLUSION

The average productivity was found to be %9 for 444 public hospitals. This means 42 public hospitals are efficient. The findings of the analyses should be considered as relative effectiveness value as the efficiency analysis shows the relativity between units in terms of the group handled (Temur, 2008).

Data set draw meaningful conclusions according to the “Golden Rule of DEA” is that number of units should be at least three times the number of outputs and inputs. (Bilsel, 2010)

Hospitals' classified in Region II and named as CRS, average value of outputs per outpatient take place between hospitals' average values of outputs per outpatient classified as Region I and Region III. Another finding that Region I hospitals' inputs per surgery and outpatient take lower value. On the other hand Region III hospitals' inputs per surgery and outpatient take higher value according to average (see Table V.1 and Table V.2).

Table V.1: Inputs rate per outpatients

	General Practitioners per outpatient	Midwife/ Nurse per outpatient	Specialists per outpatient	Bed Capacity per outpatient	Health personnel per outpatient	Other Personnel per outpatient
Region 1	0,004%	0,040%	0,009%	0,040%	0,040%	0,007%
Region 2	0,003%	0,046%	0,011%	0,044%	0,046%	0,005%
Region 3	0,005%	0,066%	0,015%	0,063%	0,066%	0,009%
Region 4	0,016%	0,103%	0,000%	0,078%	0,103%	0,012%
Region 6	0,004%	0,041%	0,009%	0,041%	0,041%	0,006%

Efficient 42 hospitals taking under examination show us, 42% of them located in Central Anatolia and Southeast Anatolia. However, Marmara Region, known as most development region of Turkey, participate with only 7%. When most inefficient 50 hospitals analyzed, seems that 22% of them located in Aegean Region. Moreover, when these hospitals RTS classification under examined, their classification appear as 44% of them IRS, 36% of them DRS.

According to the result, 84 public hospitals were found IRS and they are located in decreasing population locations. These 84 hospitals will be efficient when combined under the center hospital. In this way, their output size will be larger and this will push them to the efficient frontier.

125 public hospitals were found DRS and they are located in increasing population locations. These hospitals will be efficient by diminishing to more hospitals. Hence, their output size is too large and also getting larger by day by.

Hospital management is a politic issue. However, combining or diminishing the hospitals will bring about a rise in the hospital efficiency to 47% from 9%.

Combining the hospitals will cause public dissatisfaction. Hence, option demand is satisfied publicly by hospital beds held on reserve, along with the necessary staff and equipment (Zweifel et al., 2009). Our suggestion is given regardless of public satisfaction. There isn't any data about public satisfaction. If a survey could be done about public satisfaction, the survey's results will be used as an output at hospital efficient factors.
