LIPOSOMAL INCORPORATION OF *SATUREJA HORTENSIS L.* ESSENTIAL OIL AND *IN VITRO* ANTIMICROBIAL ACTIVITY ON ORAL MICROORGANISMS

APPROVED BY:

Assist. Prof. Dr. May Korachi (Supervisor) .....

Assoc. Prof. Dr. Yeşim Ekinci .....

Assist. Prof. Dr. Özlem Güçlü Üstündağ .....

Assist. Prof. Dr. Gülengül Duman .....

DATE OF APPROVAL: ...../ ...../ .....

This thesis is dedicated to my family for
love and support throughout my life...

ACKNOWLEDGEMENTS

At the end of my Master of Science education at Yeditepe University, I want to thank all the people who contributed to this study in some way.

I am grateful to Yeditepe University for the financial support during my MSc. education.

I would like to thank all the members of Microbiology, Immunobiology and Bioplasma Research group, without whose assistance this study would not have been successful. The informal support and encouragement of many friends at Genetics and Bioengineering department have been invaluable.

I would like to thank my supervisor Assist. Prof. Dr. May Korachi, and co-supervisor Assoc. Prof. Dr. Fatma Yeşim Ekinci for their encouraging support during the experimental and writing stages of the thesis. Furthermore, I would like to thank Assist. Prof. Dr. Gülengül Duman and Ismail Aslan for their experienced advise during the preparation of liposomes and extensive use of the Pharmacy Department's equipment and consumables.

I would also like to thank Fikrettin Şahin for providing me with *Satureja hortensis* plant without which I could not carry on with my project.

I would also like to thank my dear mother Zehra Demirbaş and my three sisters Ayşe Ekinci, Fatma Çolak and Kıymet Akçair for their unwavering support. Finally, I would like to give my heartfelt appreciation to my darling husband, Ulas Uzel without, whose support it would not have been possible to complete my Msc degree. This thesis would certainly not have existed without his and my familys' help and encouragement.

ABSTRACT

LIPOSOMAL INCORPORATION OF *SATUREJA HORTENSIS L.* ESSENTIAL OIL AND *IN VITRO* ANTIMICROBIAL ACTIVITY ON ORAL MICROORGANISMS

The use of nanotechnology in the medical industry, involves the use of carrier systems to provide bioavailability, stability and to effectively deliver antimicrobial agents. The essential oil of *Satureja hortensis* L. a popular Turkish herb, is known to have high antimicrobial activity due to the presence of carvacrol, thymol and p-cymene. The aim of this study was to incorporate, characterize and determine the antimicrobial efficacy of *S.hortensis* essential oil, loaded liposomes. Microorganisms tested were: *Aggregatibacter actinomycetemcomitans* FDC Y4, *Prevotella intermedia* ATCC 25611, *Porphyromonas gingivalis* ATCC 33277 and *Fusobacterium nucleatum* ATCC 25586, *S.mutans* and *C.albicans*. EO was extracted from *S.hortensis*, by hydrodistillation method and incorporated achieved by the Bangham method. Different types of loaded liposome (L1 and L2) formulations were prepared with phospholipid 85 G (P85G), cholesterol (CH) and stearylamine (SA) at different ratios, respectively, (P85G: CH: SA; 7:1:2 and 10:1:4). Liposomal formulations were characterized by Dynamic Light Scattering (DLS) and microscopic methods. The antimicrobial activity of L1 and L2 were examined by the Agar Well Diffusion Assay after 120 h incubation. Statistical analysis of results by way of Tukey, Anova and Dunnet tests. Both L1 and L2 showed antimicrobial effects against all test microorganisms. However, overall characterization and antimicrobial results, revealed L1 to have better properties for use against oral pathogens. A liposomal approach can be useful for containing volatile compounds that have antimicrobial effects on oral microorganisms.

Finally, liposomes incorporating *S.hortensis* L. EO, may be considered as a potential liposomal delivery system in the oral cavity in the future.

ÖZET

SATUREJA HORTENSIS L. TEMEL YAĞ ASİTLERİNİN LİPOZOM İLE BİRLEŞTİRİLMESİ VE *İN VİTRO* ORTAMDA AĞIZ MİKROORGANİZMALARI ÜZERİNDEKİ ANTİMİKROBİYAL AKTİVİTESİ

Sağlık endüstrisinde nanoteknolojinin kullanımı, taşıyıcı sistemlerin kullanımının dahil edilmesiyle biyoyararlılık, stabilite ve antimikrobiyal ajanların etkili bir şekilde taşınmasına olanak sağlamıştır. *Satureja hortensis L* uçucu yağları, yapısında bulunan carvacrol, thymol ve p-cymene' den dolayı yüksek antimikrobiyal aktiviteye sahip popüler bir Türk bitkisidir. Bu tez çalışmasının amacı, *S.hortensis L.* esansiyel uçucu yağları, lipozom ile birleştirmek, karakterize etmek, *S.hortensis L.* uçucu yağın ve yüklü lipozomların antimikrobiyal etkinliklerini belirlemektir.Test edilen mikroorganizmalar, *Aggregatibacter actinomycetemcomitans* FDC Y4, *Prevotella intermedia* ATCC 25611, *Porphyromonas gingivalis* ATCC 33277 and *Fusobacterium nucleatum* ATCC 25586, *S.mutans* and *C.albicans*'tır. Bu çalışmada *S. hortensis L.* adlı bitkiden hidrodistilasyon methodu ile uçucu yağlar elde edilmiştir ve Bangham metodu ile birleşimi sağlanmıştır. İki farklı tip yüklü lipozom (L1 ve L2) formulleri farklı oranlarda fosfolipid 85 G (P85G), Kolesterol (CH) and Stearilamin (SA) kullanılarak sırasıyla hazırlanmıştır. Formüller Dinamik Işık Saçılımı (DLS) ve mikroskobik tekniklerle karakterize edilmiştir.L1 ve L2 nin antimikrobiyal aktiviteleri Agar kuyucuk metodu kullanılarak 120 saatin sonunda test edilmiştir. Tukey, Anova and Dunnet testleri kullanılarak sonuçlar istatistiksel olarak değerlendirilmiştir. Hem L1 hemde L2 test edilen mikroorganizmalara karşı antimikrobiyal etkinlik göstermiştir. Ancak, tüm karakterizasyon ve antimikrobiyal sonuçlar, L1 in ağız patojenleri üzerinde daha etkili olduğunu ortaya koymuştur. Uçucu bileşenleri içeren lipozomlar, ağız mikroorganizmaları üzerinde faydalı bir antimikrobiyal etkinliğe sahip olabilirler.

Sonuç olarak, *S. hortensis L.*uçucu yağlarını içeren liposomların potensiyel bir lipozomlu taşıyıcı sistem olarak ağız boşluğunda gelecekte kullanılabileceği düşünülmektedir.

1. INTRODUCTION

Oral health is an important worldwide issue and contributes to the quality of life. Oral health means being free of chronic mouth and facial pain, oral and throat cancer, oral sores, gum disease, tooth decay, tooth loss and other diseases and disorders that affect the mouth and oral cavity [1, 2].

There is substantial proof connecting poor oral health to chronic conditions and systemic diseases such as periodontal disease and diabetes [1, 2], cardiovascular diseases, renal, hepatic, pulmonary, rheumatoid arthritis, adverse pregnancy effects and osteoporosis [3]. The WHO (World Health Organization) has stated that upto 90 % of school children worldwide have dental caries and 5-20 % of middle-aged adults suffer from severe periodontal (gum) disease, which may result in tooth loss. The incidence of oral cancer ranges from 1 to 10 cases per 100.000 in most countries and 40-50% of people who are HIV-positive have oral fungal, bacterial and viral infections [4].

Since dental care is an important problem for many countries in the world, cheap and effective treatments or prevention methods have gained great interest worldwide [3, 4].

2. THEORETICAL BACKGROUND

2.1. ORAL DISEASES

Dental diseases affect the oral cavity most of which involve the teeth and surrounding supportive structures, collectively known as the periodontium (gingiva, ligaments, membrane, bone) (Figure 2.1) [5].

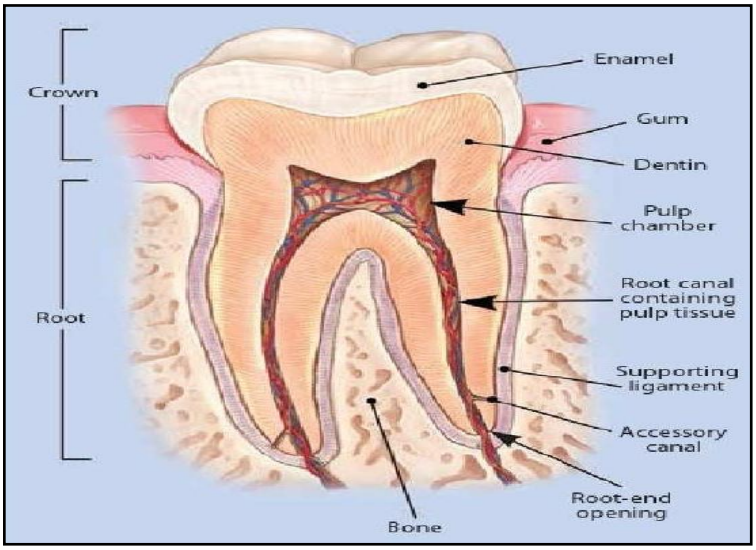

Figure 2.1. The anatomy of a tooth [5]

Dental pathology commonly influences both hard and soft tissues of oral cavity. Although both categories of disease start when microbes adhere to the tooth surface and produce dental plaque, their outcomes can vary. Figure 2.2 is a summary of the events leading to dental caries, periodontal diseases, and bone and tooth loss [5].

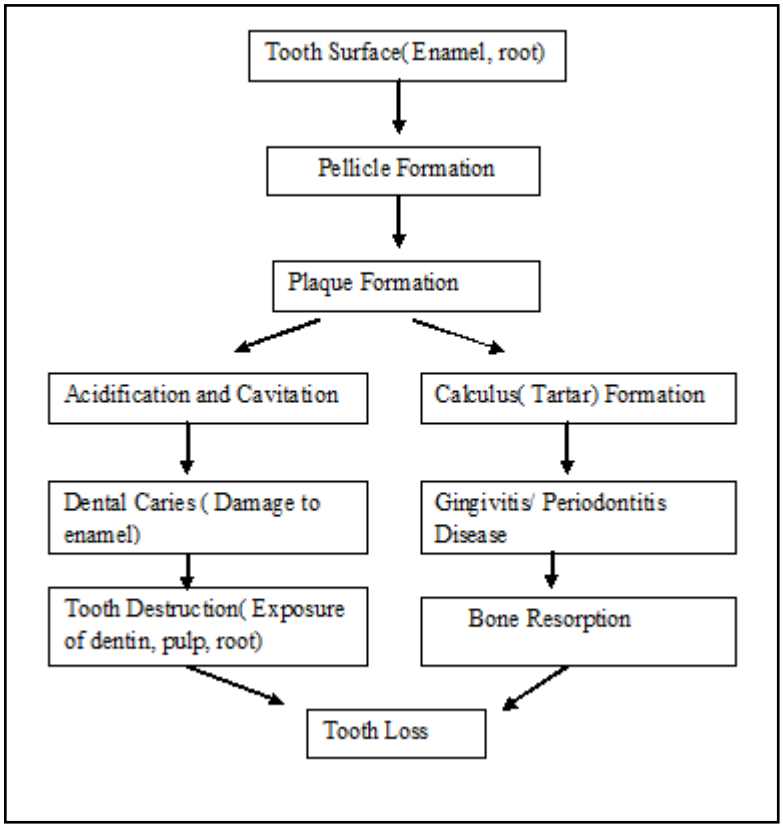

Figure 2.2. Events and Diseases Resulting in Tooth Loss [5]

2.1.1. Hard Tissue Disease: Dental Caries

Dental caries is the most common human disease. It is a complex mixed infection of the dentition that gradually destroys the enamel and often lays the background for the damage of deeper tissues. It occurs most often on tooth surfaces that are less accessible and harder to clean and on those that provide pockets or crevices where bacteria can cling. Caries commonly develops on enamel pits and fissures, especially those of the grinding surfaces, though they can also occur on the smoother crown surfaces and subgingivally on the roots.

Although they are not classified as life threatening diseases, dental caries are prevalent and costly problems for suppliers of health services. In order to decrease the prevalence of caries, an improved understanding of the role of the microorganisms in dental diseases is needed [6]. The tooth surface is covered with a biofilm slime layer consisting of millions of bacterial (cells) microcolonies, salivary polymers, fluid channels and complex communication systems [7]. This biofilm can easily reach a thickness of hundreds of cells

on the surfaces of the teeth. The formed biofilm, also called plaque, provides an excellent adhesion site for the colonization and growth of many bacterial species.

Over the years, several views have been put forth to explain how dental caries originate. At various times it has been believed that sugar, microbes and acid cause teeth to rot. Germ-free animals eventually displayed that no single factor can account for caries. Caries development occurs in many phases and requires multiple interactions involving the anatomy, physiology, diet, and bacterial flora of the host. The principal stages (Figure 2.3) in the formation of dental caries are pellicle formation, plaque formation, acid production and localization and enamel corrosion [5].

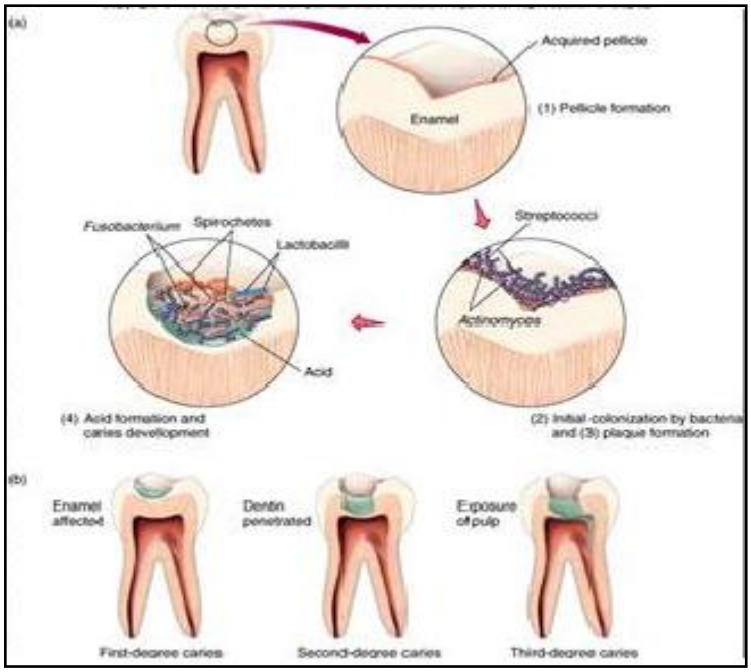

Figure 2.3. Stages in plaque development and cariogenesis. The macroscopic and microscopic appearance of plaque a. A microscopic view of pellicle and plaque formation, acidification and destruction of tooth enamel. b. Progress and degrees of cariogenesis [5]

2.1.2. Plaque Formation

Dental plaque is a biofilm community that accumulates through sequential and ordered colonization of multiple oral bacteria [8]. Three steps are involved in the development of dental plaque [6]. First, salivary molecules such as salivary proteins, believed to be

primarily secreted from *S. mutans* are attached to the enamel. This coats the enamel with a complex mixture of components that include glycoprotein, acidic proline-rich proteins, mucins, bacterial cell debris, exoproducts, and sialic acid [6]. Through this matrix, fluid channels form, that provide nutrients, oxygen, communication, genetic exchange, production of inhibitory factors and quorum sensing, which determines the metabolism and composition of the biofilm residents [7, 8]. Quarum sensing is a signaling system essential for genetic competence in *Streptococcus mutans*.[9]

Second, bacterial cells attach to this acquired pellicle via several specific cell-to-surface interactions [9]. The biofilm formation of 3 main primary colonizers, *S.mutans, S. sanguis* and *A. viscosus* [10], are influenced by a number of environmental factors, like osmolarity and pH of the oral cavity and carbon source [9]. These primary colonizers have an affinity for the matrix and their adhesion to it paves the way for the adherence and accumulation of other microorganisms.

During the third stage, other bacterial species (late colonizers) usually anaerobic bacteria such as *Prevotella* and *Porphyromonas* species [7], adhere to the primary colonizer by cell-to-cell interactions. In addition to cell-to-cell interactions, metabolic interactions and quorum sensing are also important for biofilm formation and development.

The exact process of these interactions is still unknown but it is believed that quorum sensing plays a role. Subsequent bacterial growth on tooth surface leads to the formation of a biofilm on the teeth, also called, dental plaque [9, 11]. The microorganisms live with one another in commensal or mutualistic symbiotic relationships [12]. Typically, anaerobic bacteria would succumb to high levels of oxygen, but with the redox reactions they are able to survive. This commensal relationship allows a mixture of aerobic and anaerobic bacteria to live in the same area. The formation begins by the adsorption of early colonizers onto an acquired pellicle through chemical processes [13].

Primary colonizer, *S. mutans* is a Gram-positive bacterium, non-motile, facultative anaerobe. *S. mutans* gives its name to a group of seven firmly connected species all together associated with the mutans streptococci. The original habitats of *S. mutans* are the mouth, pharynx, and intestine [14]. It can thrive in temperatures between 18-40°C.

S. mutans is a strong acid producer and hence causes an acidic environment creating the risk for cavities [15]. Virulence factor of *S. mutans* in cariogenicity is its ability to attach to the tooth surface and form a biofilm [16]. If mature plaque is not removed from sites that readily trap food, it usually evolves into a caries lession. The role of plaque in caries development is related directly to streptococci and lactobacilli, which produce acid as they ferment dietary carbohydrates. If this acid is immediately flushed from the plaque and diluted in the mouth, it has little effect. However, in the denser regions of plaque the acids can accumulate in direct contact with the enamel surfaces and lower the ph to below 5, which is acidic enough to begin dissolving the calcium phosphate of the enamel in that spot. This lesion remains localized in the enamel (first degree caries) and can be repaired with various inert material (fillings). Once degradation has reached the level of dentin (second-degree caries) tooth destruction speeds up, and the tooth can be rapidly destroyed. Exposure of the pulp is attended by severe tenderness and toothache and the chance of saving the tooth is diminished [5].

2.1.3. Soft-Tissue (Periodontal) Diseases

Periodontal diseases generally affect 97-100 % of the worldwide population, and have some manifestations by age 45. Most types are due to bacterial colonization and varying degrees of inflammation that occur in response to gingival damage. The most common predisposing condition occurs when the plaque becomes mineralized (calcified) with calcium and phosphate crystals. This process produces a hard porous substance called calculus above and below the gingiva, which can induce varying degrees of periodontal damage [5].

Calculus and plaque accumulating in the gingival sulcus causes abrasions in the delicate gingival membrane and the chronic trauma causes a pronounced inflammatory reaction. The damaged tissues become a portal of entry for a variety of bacterial residents. These include genera such as; *Actinobacillus, Porphyromonas, Bacteroides,* and *Fusobacterium* and numerous spirochetes. The anaerobic, gram-negative bacteria in these infections out numbers aerobes by 1 to 100. In response to the mixed infection, the damaged area becomes infiltrated by neutrophils and macrophages and later by lymphocytes, which cause further inflammation and tissue damage. The initial signs of gingivitis are swelling,

loss of normal contour, patches of redness and increased bleeding of the gingival spaces. Pockets of varying depth also develop between the tooth and the gingiva. If this condition persists, a more serious disease called Periodontitis results (Figure 2.4). This is the natural extention of the disease into the periodontal membrane and cementum. The deeper involvement increases the size of the pockets and can cause bone resorption severe enough to loosen the tooth in its sockets. If the condition is allowed to progress, the tooth can be lost [5].

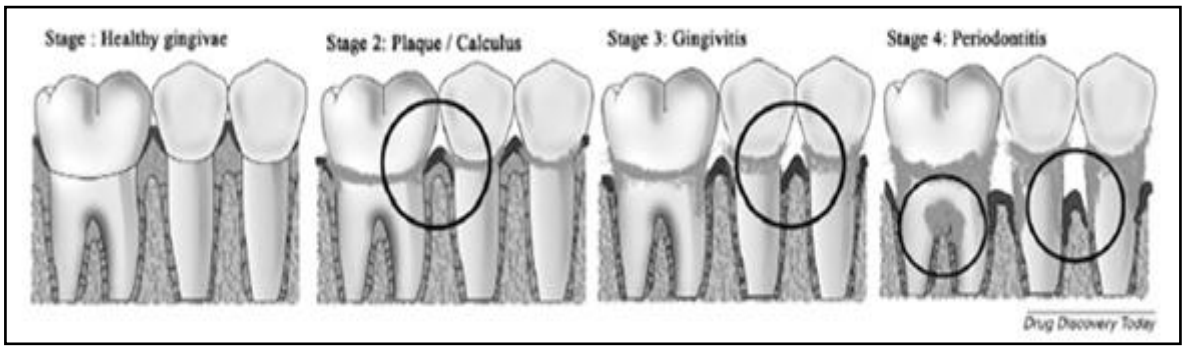

Figure 2.4. The image of disease progression from healthy gingiva to periodontitis [17]. Stage1. Healthy gum tissue, Stage 2. Plaque formation due to bacterial invasion, Stage 3. Bacterial toxins irritate gums and trigger host-mediated responses that lead to gingivitis, Stage 4. Destruction of gingiva and bone that support the tooth leading to periodontitis [17]

2.2. ROLE OF MICROORGANISMS IN ORAL DISEASE

Dental caries and periodontal diseases are among the most important treatable global oral diseases [4]. The relationship between humans and their microflora is complex. The mouth contains a diversity of surfaces for colonization, including the tongue, teeth, gingiva, palate, and cheeks and it provides numerous aerobic and anaerobic and micro-aerophilic microhabitants for the estimated 700 different oral species with which human coexist. The habitat of the oral cavity is warm, moist, and greatly enriched by the periodic infusion of food. In most humans, this association remains in balance with little adverse effect, but in people with poor oral hygiene, it teeters constantly on the brink of disease. Dental caries is a supra-gingival event [18]. While conversely, periodontal diseases are sub gingival cases

that have been related to anaerobic Gram-negative bacteria such as *Porphyromonas gingivitis, Actinobacillus, Prevotella, Fusobacterium sp* [19, 20].

2.3. ORAL MICROORGANISMS

The oral microbiota is complex and has some features that make it a unique habitat. Viruses, fungi, protozoa and bacteria colonize many oral sites including the tongue, oral mucous membranes, subgingival and supragingival tissues, and teeth [21, 22, 23]. Several microorganisms are present on the external surfaces of the human body and most of these commensal microbes are in harmony with the host. The oral microbiota, however, are the only part of the human body whose commensal microbes cause disease [4].

The human oral cavity is also called the human oral microbiome. This is because the human oral cavity can contain several environments at a given moment that could vary from tooth to tooth [4]. Additionally it has been estimated that the number of bacterial species that reside in the mouth is approximately 25,000 [5]. This is in contrast to the previously estimated 700 + species [6]. Studies have found that out of the 25,000 species that exist in the oral cavity, about 1000 species can exist as part of the dental biofilm ecosystem [7, 8]. 1000 species were identified with the help of developed molecular and microbial techniques [8].

Their composition varies in different sites in the oral cavity, e.g. a large and more diverse microbial load is present on the dorsum of the tongue. Most of these microbes are harmless, but under certain conditions, some can cause oral infections like caries or periodontal diseases [15].

2.3.1. Bacteria

Bacteria are the most common microorganisms of the oral cavity [24]. The oral cavity consists of different types of Gram positive and Gram negative, obligate aerobes and facultative and obligate anaerobes [9].

Bacterial species have been identified in the healthy and diseased sites of the oral cavity [9] by culture methods and culture-independent molecular methods. Approximately 36 phyla/divisions within bacterial domains have been determined in the mouth [25] and eight phyla that are found frequently in the mouth are *Actinobacteria, Bacteroidetes, Firmicutes, Fusobacteria, Protebacteria, Spirochaetes, 'Synergistes'* and TM7. Amongst these, species of *Actinobacteria (Actinomyces naeslundii), Bacteroidetes (Porphyromonas gingivalis, Porphyromonas endodontalis, Tannerella forsythia, Prevotella intermedia, Prevotella nigrescens, Capnocytophaga ochracea, Capnocytophaga gingivalis), Firmicutes (Streptococcus mutans, S. mitis, S. sobrinus, S. oralis, S. gordonii, S. sanguinis), Fusobacteria (F. nucleatum), Protebacteria (Aggregatibcater actinomycetemcomitans*) and *Spirochaetes* (*Treponemes denticola* and *T. medium*) were shown to play a role in dental plaque formation and in plaque associated oral diseases [26].

2.3.2. Fungi

Yeasts are commensal microorganisms in the mouth [26]. *C. albicans* is the major causative agent of human oral fungal infections causing oral candidiasis. It is a major opportunistic pathogen of immunocompromised hosts, including AIDS patients, those undergoing chemotherapy, tissue transplants or patients with central venous catheter [27]. *C.albicans* colonizes many surfaces in the oral cavity such as tooth surfaces, tongue, and epithelial cell of the cheek [28].

2.3.3. Protozoa

Protozoa are not present in the normal oral cavity, they can only be seen in the absence of oral hygiene. For instance, *Entamoeba gingivalis* and *Trichomonas tenax* are protozoa species and can be found between the gingival pocket and teeth [29].

2.3.4. Viruses

In addition to bacteria, many kinds of viruses have been found in the mouth, such as *Herpes simplex* virus, Cytomegalo or *Epstein-Barr* virus. Although their prevalence has increased in the case of oral diseases such as periodontitis and periodontal abscesses, these viruses

have been encountered in healthy subjects [30, 31]. These viruses transmit through sexual contact [32] and breastfeeding [6, 32].

2.4. PREVENTION AND TREATMENT OF ORAL DISEASES

2.4.1. Mechanical Methods

Dental diseases can be controlled by careful mechanical oral hygiene [33, 34]. The main way of preventing oral diseases is adequate daily tooth brushing [35]. Daily removal of pre-formed biofilms by tooth brushing and flossing can stop the colonization of pathogenic bacteria [16, 28, 36, 37]. Despite its important role in the prevention of gingivitis and periodontitis, mechanical plaque control is not accurately practiced by most individuals [33, 38].

Further plaque formation causes the hardest plaque, which is named calculus or tartar. This calculus cannot be removed easily from the tooth surface by brushing techniques [39]. If tooth brushing cannot clean the area, mechanical scaling and root planning should be applied [40].

Previous studies have shown that periodontal therapeutic methods such as root planning and scaling have reduced inflammation and bleeding of the gingivia in the oral cavity [41, 42, 43]. With the development of technology, a lot of alternative methods are employed to kill periodontal pathogenic bacteria and to disrupt their biofilm matrix. Currently, the most important technique is photodynamic therapy [44]. This therapy includes the activity of solar light on pathogenic microorganisms, which are immersed by specific dyes [44].

2.4.2. Chemical Methods

A wide range of agents have been formulated into oral care products in order to enhance their plaque control potential [33, 34]. Scientists and dentists have been using systemic chemotherapeutic agents in combination with mechanical methods to prevent dental plaque efficiently. Chemical anti-plaque agents in mouth rinses and toothpastes reach the soft tissue surfaces, improving the control of biofilm growth on these surfaces [45].

Chlorhexidine (CHX) is the most conventional antiseptic agent in oral products. It is widely used in clinical practice as a skin and mucous membrane antiseptic and a disinfectant [40]. It is a biphenyl compound which has broad spectrum of activity against Gram-positive and Gram-negative bacteria and yeasts. It also decreases plaque, dental caries and gingivitis due to its cationic structure [40, 46]. CHX is bactericidal and at high concentrations causes lethal damage to the bacterial membrane. Conversely, at low concentrations could be bacteriostatic [40, 46]. The efficiency of the CHX influences the cell wall and damage the LPS layer and cytoplasmic membrane. Therefore, the leakage of the cell components cause death of bacteria at sub lethal concentrations, CHX can interfere with the metabolism of oral bacteria by inhibiting sugar transport and acid production in cryogenic *streptococci* [46] and various membrane functions in *Streptococci*, including enzymes responsible for maintaining an appropriate intracellular pH. The disadvantages of CHX is that it is a chemical based product and cannot be used long term (1 week), as it can cause discolouration of the teeth (yellowing).

Listerine is an antiseptic mouth rinse, which consists of a mixture of essential oils (menthol, thymol, methyl salicylate and eucalyptol) and ethanol (21 per cent) which helps dissolve the essential oils. Listerine was formulated as a surgical antiseptic in 1879. Now, however, it is consumed also for oral care. Listerine is a well-known efficient and anti-plaque and anti-gingivitis therapeutic solution.

The action of listerine was reported as bacterial cell wall destruction, bacterial enzyme inhibition and extraction of bacterial lipopolysaccharides [47]. Moreover, it kills the pre-formed accumulation and prevents accumulation of the pathogenic microorganisms [48, 49]. The disadvantages of Listerine are that it has an unpleasant taste with a burning sense on the mucosa. Studies indicate that prolonged consumption of this mouth rinse can induce some resistant species in the dental plaque and inconvenient oral pathogens [48].

Triclosan (5-chloro-2-(2, 4-dichlorophenoxy) phenol) is an oral care product and has a broad spectrum of antimicrobial, anti-inflammatory activity [50]. Many contemporary consumer and personal health-care products (deodorants, toothpastes, mouth washes), household items (plastics and textiles) include triclosan [50]. In the literature, triclosan demonstrated some anti-plaque and anti-gingivitis effects in a mixture with complementary

antimicrobial agents, such as zinc [50]. The bacteriostatic activity of triclosan was observed at concentrations ranging between 0.025 and 100 μg/mL., whereas bactericidal activity was observed at higher concentrations. At bactericidal concentrations, it destroys the bacterial cell wall functions, leading to leakage of the cellular contents and eradicates the bacteria species individually. Some studies demonstrated that gram negative bacteria species and some intestinal, dermal and environmental species can establish resistance to triclosan and some side effects, such as allergies, and toxicity in children [50].

Fluoride is synthesized chemically and present in low concentrations in drinking water, sea water and food. Many studies showed that fluoride has an anti-cryogenic effect [51, 52]. That is why tooth pastes and mouth rinse consisting of fluoride are used and sold worldwide and tap water is fluoridated in the USA and the UK [53]. However, there are many opposing ideas on the consumption of fluoride for human health. Antagonists support that fluoride is a toxic chemical; therefore, it should not be used in tap water, toothpastes, and mouth rinses [54]. The level of fluoride which is taken into the body is very critical. An adult can digest 0.042 mg/kg of fluoride whereas a child can digest 0.127 mg/kg fluoride daily [55]. Some studies have indicated that an intake of high levels of fluoride lead to some side effects, such as dental and skeletal fluorosis, immunotoxicity, carcinogenicity, genotoxicity, reprotoxicity, renal toxicity, and gastrointestinal tract toxicity [51, 55].

Sodium hypochlorite (NaOCl) is the most common household bleach and cleanser. It has been integrated into oral medicines to treat periodontal disease [56] It has been shown that 0.01 % NaOCl in many oral products may be helpful for prevention of dental plaque and oral biofilm [56, 57, 58]. However, high concentrations of sodium hypochlorite can cause irritation of the mucous membrane [56].

Povidone-iodine is a povidone (polyvinylpyrrolidone) polymer. Povidone-iodine has demonstrated sufficient action against certain microorganisms. While, it does not irritate the oral mucosa and tongue, or discolorize teeth [58], some studies have shown that mouth rinses that include 1% of povidone iodine do not kill plaque forming microorganisms [55, 59].

Antibiotics are synthetic and natural organic constituents that kill and restrict particular microorganisms at low concentrations. Many antibiotics that are widely used in dentistry, include: penicillin, metronidazole, doxycycline, tetracycline, clindamycin and amoxicillin [56]. However antibiotics have the risk of causing microbial resistance and have some reverse impacts such as gastrointestinal disturbances, headache, dizziness and hypersensitivity [60, 61].

With the many disadvantages of current methods [44, 61], alternative natural plant products are considered a good alternative to current therapies described [62].

2.4.3. Phytotherapy

2.4.3.1. Definition Of Phytotherapy And Its Applications

All natural extracts have a wide range of bioactive components such as lipids phytochemicals, flavors, fragrances, and including pigments (thymol, carvacrol, camphor, fenchone, thuyone, caryophyllene, logifolene, curcumenes, etc) [63]. Plant extracts are widely employed for different applications, exclusively as health promoting elements used in the formulation of food additives, nutraceuticals, pharmaceuticals and cosmetics [64]. Aromatic plants have been widely consumed since ancient times. However, over the last few decades researchers and scientists have been interested in investigating their biological activities and studying them for traditional treatment of many diseases [65- 69].

2.4.3.2. Phytotherapy In The Global Market

In rural areas of the world, plants are still being used as the main source of medicine therapy [70]. Approximately 80 % of the people use traditional medicines for treatment in developing countries [70, 71]. Since microorganisms are becoming increasingly resistant to therapeutic agents such as antibiotics this has led to interest in the discovery of novel anti-infective ingredients.

According to the WHO, traditional plant products have economical importance for pharmaceutical companies due to reduced cost of screening. There are approximately 121 plant based prescription drugs in the world [2, 72, 73] and the global market of these drugs have been predicted at $43 [2, 73] billion. In developing countries including Turkey, plant

based therapies also known as traditional medicine, are widely used due to their low cost and easy access [2].

2.4.3.3. Use Of Essential Oil

Essential oils are volatile, natural, complex compounds characterized by a strong odour [63]. They can be synthesized by aromatic plants and all plant organs, buds, flowers, leaves, stems, twigs, seeds, fruits, roots, wood or bark where they are stored in secretary cells, cavities canals, epidemic cells or glandular trichomonas as secondary metabolites. They are liquid, seldom coloured, soluble in lipid organic solvents with generally a lower density than water [63, 74].

Essential oils are extracted from different aromatic plants generally from warm countries like Mediterranean and tropical countries where they represent an important part of the traditional pharmacopoeia [74]. They have been found to have aseptic, bactericidal, virucidal, and fungicidal properties [75-78].

In nature, essential oils play an important role in the protection of the plants as antibacterials, antivirals, antifungals, insecticides and against herbivores by reducing their appetite for such plants. In addition, they may attract some insects to favour disperison of pollens and seeds or repel undesirable predators [74].

At present, around there are 3000 known essential oils, 300 of which are commercially important specifically for the pharmaceutical, agronomic, food, sanitary, cosmetic and perfume industry [79-83].

2.4.3.4. Essential Oil Extraction Techniques

There are several extraction methods for obtaining essential oils from different parts of plants. These methods provide extracts with different composition and yield [83]. These extraction methods include: water distillation (or hydro distillation), steam-distillation, cold pressing (expression), solvent extraction, supercritical carbon dioxide extraction, microwave-assisted solvent extraction (MASE) and solvent free microwave extraction (SFME) [81-91].

2.4.3.5. Chemical Composition Of Essential Oils

Essential oils are very complex natural mixtures which can contain approximately 20-60 components at varying concentrations. They are characterized by two or three major components at fairly high concentrations (20-70 %) compared to others components present in trace amounts. For example, carvacrol (30 %) and thymol (27 %) are the major components of the *Origanum compactum* essential oil [92]. Essential oil molecules are composed of mainly three atoms: carbon, hydrogen and oxygen bonded in a variety of ways. They are made of four major components namely terpenes, terpenoids, aromatic constituents and aliphatic constituents all having low molecular weight. Based on biosynthesis, these component molecules divide into two groups. First one, terpene hydrocarbons, (monoterpenes and sesquiterpenes) and terpenes modified by oxygen are called terpenoid. Second one is phenylpropane derivatives and they behave like terpenes. Also, phenylpropane derivatives organise into two groups; Aromatics and Aliphatics. They may exist in the form of alcohols, acids, esters, epoxides, aldehydes, ketones, amines, sulfides etc [93-97].

Terpenes are the main constitutents of essential oils in plants in nature and differ structurally and functionally with combinations of several 5-carbone-base (C5) units called isoprene. They are classified according to the number of isoprene units; monoterpenes (2 isoprene units), sesquiterpenes (3 isoprene units) , diterpenes (4 isoprene units), triterpenes (6 isoprene units) and tetraterpenes (8 isoprene units) [79, 97, 98]. The monoterpenes are formed from the coupling of two isoprene units (C_{10}). They are the most representative molecules constituting 90 % of the essential oils and allow a great variety of structures [98]. Also, Table 2.1 represents the functional groups in the essential oils.

The main terpenes are the monoterpenes (C_{10}), and sesquiterpenes (C_{15}) but hemiterpenes (C_5), diterpenes (C_{20}), triterpenes (C_{30}) and tetraterpenes (C_{40}) also exist. Terpenoids are the terpenes containing oxygen molecules or terpenes with functional group [97, 98]. Many terpenes are hydrocarbons, but oxygen-containing compounds such as alcohols, aldehydes, or ketones are called a terpenoid. Their building block is the hydrocarbon isoprene $CH_2=C(CH_3)-CH=CH_2$ terpene hydrocarbons therefore have molecular formulas $(C_5H_8)_n$.

Table 2.1. Monoterpenes and sesquiterpenes according to their functional groups [97, 98]

	Terpene and Terpenoids	
Functional group	Monoterpenes	Sesquiterpenes
Carbure	Acyclic: Myrcene, Ocimene Monocyclic: Terpinenes, p-Cymene, Phellandrenes Bicyclic: Pinenes, Camphene, Sabinene	Azulene, β-Bisabolene, Cadinenes, β-Caryophyllene, Logifolene, Curcumenes, Elemenes, Farnesenes, Zingiberene
Alcohol	Acyclic: Geraniol, Linalol, Citronellol, Lavandulol, Nerol Monocyclic: Menthol, α-Terpineol, Carveol Bicyclic: Borneol, Fenchol, Chrysanthenol, Thuyan-3-Ol	Bisabol, Cedrol, B-Nerolidol, Farnesol, Carotol, B-Santalol, Patchoulol, Viridiflorol
Aldehyde	Acyclic: Geranial, Neral, Citronellal	
Ketone	Acyclic: Tegetone Monocyclic: Menthones, Carvone, Pulegone, Piperitone Bicyclic: Camphor, Fenchone, Thuyone, Ombellulone, Pinocamphone, Pinocarvone	Germacrone, Nootkatone, Cis-Longipinan-2,7-Dione, β-Vetinone, Turmerones
Ester	Acyclic: Linalyl Acetate Or Propionate, Citronellyl Acetate Monocyclic: Menthyl Or α-Terpinyl Acetate Bicyclic: Isobornyl Acetate	
Ether	1,8-Cineole, Menthofurane	
Peroxyde	Ascaridole	
Phenol	Thymol, Carvacrol	

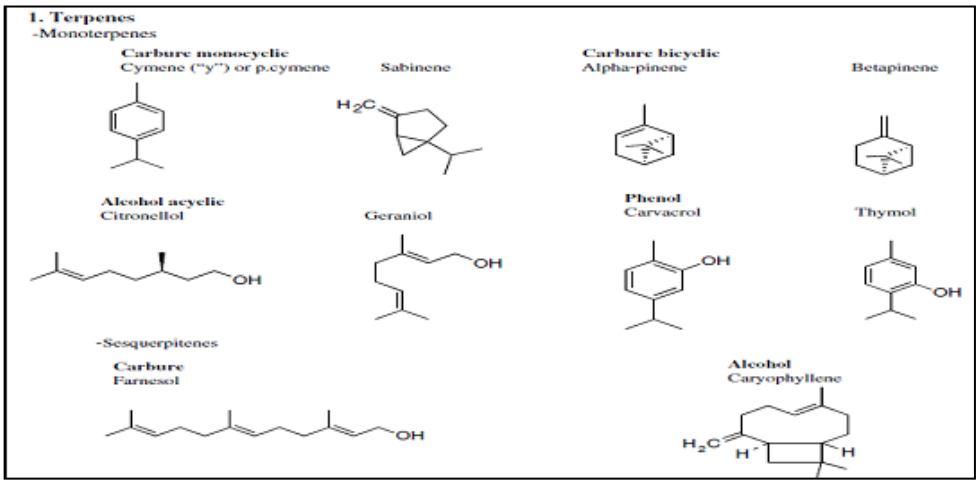

Figure 2.5. Chemical structures of some components of EO [97, 98]

Aromatic constituents derived from phenylpropane, are found less frequently than the terpenes. Aromatic compounds comprise of: Aldehyde, Alcohol, Phenols, Methoxy derivatives and Methylene [97, 98].

Aromatic constitutes of essential oils are derived from phenyl propane and they are present in plants at lower amounts than terpenes [97- 99]. Some plants containing aromatic compounds are cinnamon, clove, fennel, anise, etc. As monoterpenes and sesquiterpenes, naming of aromatic constituents depends on functional group that they contain (Table 2.2).

Aliphatic Compounds are extracted from plant by means of steam distillation methods. These compounds have a very low molecular weight such as hydrocarbons, acids (C3-C10), alcohols, aldehydes, acyclic esters or lactones [97, 99].

Nitrogeneous or sulphured components such as glucosinolates or isothiocyanate derivatives are also characteristic as secondary metabolites of diverse plants or of torrefiel, grilled or roasted products [79, 97].

Table 2.2. Aromatic constituents according to functional groups [97]

Functional group	
Alcohol	Cinnamic Alcohol
Aldehyde	Cinnamaldehyde
Phenol	Chavicol, Eugenol
Methoxy derivatives	Anethole, Elemicine,Estragole, Methyleugenol
Methylenedioxy compound	Apiole, Myristicine, Safrole

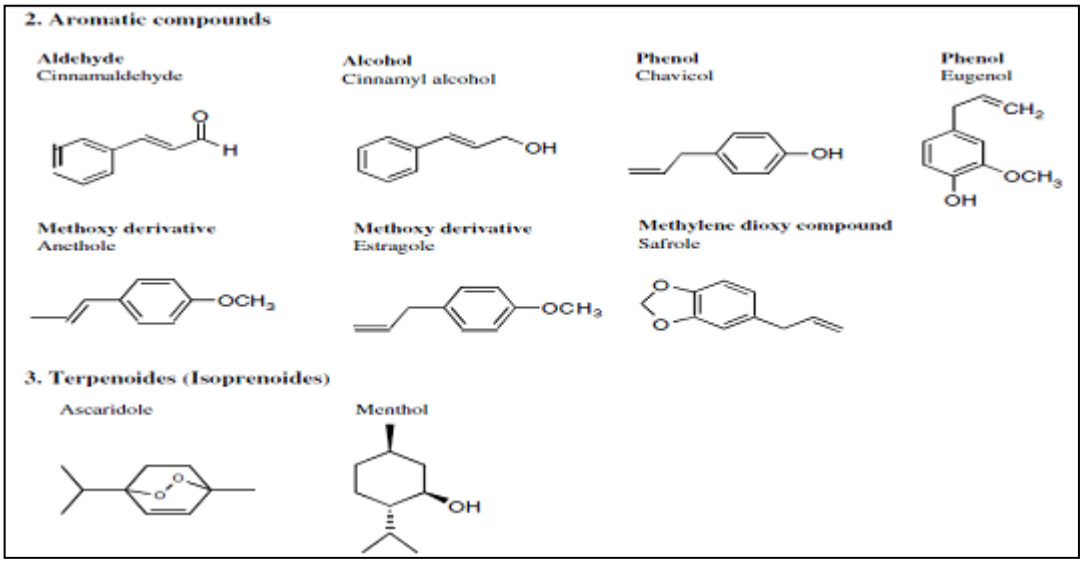

Figure 2.6. Chemical structures of some components of EO [97, 98]

2.4.3.6. Mechanisms Of Antimicrobial Activities Of Essential Oils

The components of essential oils, both major and minor, play an important role in its biological activities [94, 100]. Variation in the antimicrobial performance of the EO is related to differences in the volatile composition of the oil [95, 96, 97]. Several spices particularly garlic, ajowain, black pepper, clove, ginger, cumin and caraway are used extensively in the diet and medicine [96]. Studies have demonstrated that some essential oils(mint, lemon, bergamot EO of stems, leaves and flowers) can have high antimicrobial activity against a wide spectrum of both Gram (-) and Gram (+) pathogenic bacteria and fungal strains [97, 101, 102, 103, 104, 105, 106]. The antimicrobial activity is attributed to the phenolic content, which is present at very high percentages [107, 108]. An important characteristic of EOs and their components is their hydrophobicity, which enables them to enter between the lipids of the bacterial cell membrane and mitochondria, disturbing the structure and rendering them more permeable [109], thereby causing swelling. Increases in cytoplasmic membrane permeability appear to be a consequence of the loss of the cellular pH gradient, proton motive force and decreased ATP levels, resulting in the death of the cell [110, 111]. Leakage of ions and other cell contents can then occur [112]. Although a certain amount of leakage from bacterial cells may be tolerated without loss of viability, extensive loss of cell contents of, critical molecules such as ATP and ions lead to death [113]. It has been seen that the essential oil that has the strongest antibacterial properties

against pathogens, contain a high percentage of phenolic compounds such as carvacrol, eugenol, and thymol [63, 74, 101, 114, 115]. The biological precursor of carvacrol, p-cymene, is hydrophobic and causes an expansion of the cytoplasmic membrane. When combined with carvacrol in vitro, p-cymene incorporates into the cytoplasmic membrane, facilitating transport of carvacrol across the membrane [116]. Thus, the antimicrobial activity of carvacrol is increased by the presence of its precursor p-cymene, owing to the described synergistic effect [63].

Components of essential oils also appear to act on cell proteins embedded in the cytoplasmic membrane [117]. Enzymes such as ATPases are known to be located in the cytoplasmic membrane and to be bordered by lipid molecules. Cyclic hydrocarbons could act by two different mechanisms; lipophilic hydrocarbon molecules could accumulate in the lipid bilayer and alter the lipid protein interaction or alternatively, direct interaction of the lipophilic compounds with hydrophobic parts of the protein is possible [118].

Antimicrobial action of essential oils and their components have been generally thought against membrane structure and function [119]. Figure 2.7 shows the possible targets of essential oils on bacterial cell.

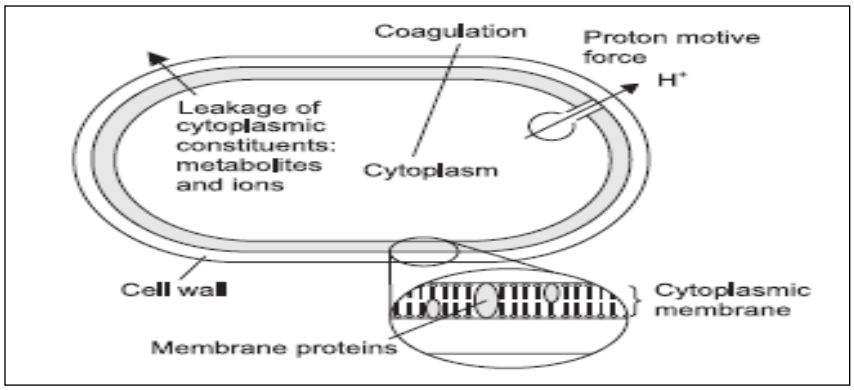

Figure 2.7. Targets of essential oil in the bacteria cells [99, 120]

EO acts on the bacterial cells by the cell wall, damaging the cytoplasmic membrane and membrane protein, causing leakage of cell contents, coagulation of cytoplasmic and depletion of the proton motive force [109, 113, 121].

2.4.3.7. Synergism And Antagonism Between The Components Of Essential Oils

The antibacterial activity of EO can be related to the chemical constituents of its component, the proportions in which they are present and their interactions [122, 123]. When the combined effect of the substances is higher than the sum of the individual effects, this is synergy. Antagonism is observed when a combination shows less effect compared to the individual applications [63].

Synergetic effects of some compounds, in addition to the major components in the EOs have been shown in some studies [99]. Applications of a certain combination of carvacrol-thymol can improve the efficacy of EOs against pathogenic microorganisms [124, 125]. Some studies have demonstrated that whole essential oil has a greater antimicrobial activity than the major components mixed [126]. This suggests that minor components are critical to the activity and may have synergetic effect [126]. The two structurally similar major components of oregano essential oil, carvacrol and thymol were found to give an additive effect when tested against Gram-positive and Gram-negative bacteria [127].

Synergism between carvacrol and its biological precursor acts on the cell wall. Even though p-cymene is a very weak antimicrobial agent, it destroys bacterial cell membranes at greater extent than carvacrol does. By this mechanism p-cymene probably enables carvacrol to be more easily transported in to the cell so that a synergetic effect is achieved when two are used together [116].

2.4.3.8. Satureja hortensis L.

The genus *Satureja (Lamiaceae)* is native to the Mediterranean region of Europe, western Asia, North Africa, The Canarian Islands and South America. The genus includes about 15 species of herbaceous perennial and subshrubs that can be found in Turkey. Five of them are endemic, including *S. aintabensis* [125, 128, 129, 130].

Figure 2.8. Images of *Satureja hortensis L* herbs [131]

Individual *Satureja* species (also known as summer savory) are locally named as ‘keklik otu’, ‘kılıç otu’, ‘firubu’,’çatlı’ or ‘kekik’ in the territory where they grow and are consumed as culinary or medical herbs in different regions of Turkey. Figure 2.8 represents the aerial parts of *Satureja* species [131]. In addition to summer savory's aromatic leaves, this fast-growing plant is spread all over with clouds of small pink or white flowers in spikes [128, 130]. It is used in the food industry as an aromatic and flavoring substance and is said to have anti-inflammatory antioxidant, antibacterial ,antifungal, fungicidal, antiviral, antispasmodic, and antidiarrhoel effects [80, 93, 94]. *S. hortensis* is also used as a muscle pain reliever, tonic for cramps, nausea and digestion by local people [68].

Savory species produce antimicrobial secondary metabolites, essential oils, either as a part of their normal program of growth and development or in response to pathogens attack or stress [132, 133, 134, 135]. Phytochemical studies on *S. hortensis* displayed that carvacrol and other monoterpene hydrocarbons in its essential oil, (flavonoids like apigenin and apigenin-4’-methyl ether and phenolic acids), were the main components of the aerial parts [136, 137]. The main constituents of the essential oil of *S.hortensis* are phenols, carvacrol and thymol as well as p-cymene, β-caryophyllene, linalool and other terpenoids [138]. The high percentage of carvacrol primarily accounts for its biological actions [137]. The chemical composition and yield of essential oil are influenced by many exogenous factors such as geographical origin, altitude, climate, soil make-up, variants of the species, part of

the plant used to extract oil, time of harvest, crushing intensity, distillation method, extraction time and duration of storage [107, 139, 140, 141]

According the literature review, *Satureja* species are well-known aromatic and medical herbs. Aromatic plants owing to their antiseptic properties, are used as spices and natural food preservatives, in the perfume industry, for aromatherapy and for different medical purposes. Among the aromatic plant species, the genus *Satureja L*. engages a special position. *Satureja* includes more than 30 species belonging to the family of Lamiceae. Also, distribution of the genus *Satureja* overlaps the region of southern and south-eastern Europe, Asia minor and Nothern Africa, with the predominance in the Mediterranean. It is known that the chemical composition and yield of EO are affected by several factors such as geographical position, altitude, climate, soil composition, drying method, extraction method.

Together with exogenous factors, the quality and quantity of EO are also affected by endogenous factors [155]. Many study concluded that drying of the aerial parts of *Satureja hortensis* in shady or dark places is more efficient, while extraction of EO by hydrodistillation is recommended. Beside this, many study showed that the highest content of phenolic compounds was in the oil isolated from material collected during the full flowering stage [147]. A literature review of studies on *Satureja* EOs including collection site, part of the plant, drying conditions, extraction methods, chemical compositions and biological activities are presented in Table 2.3.

2.5. LIPOSOMES

2.5.1. Definition, Formations and Classification of Liposomes

Liposomes were first investigated by Bangham and co-workers in 1965 at Cambridge University [156] and the first drug based on liposomes was presented to the market in 1996 [156, 157]. Liposomes are spherical microscopic dispersions with a thin lipid like membrane with an aqueous cavity at their centre. The cover is made of concentric biomolecular sheets (lamellae) composed of phospholipids, the main constituents of cell membranes. Phospholipids are amphipilic with a hydrophilic head and a lipophilic tail. In aqueous solutions, they resemble artificial cell membranes. The fatty acid tails are non polar and arranged towards the interior of the membrane, whereas the hydrophilic heads line up outward of the membrane. The number of the coating sheets may vary, leading to

typical sizes of 15-3500 nm, depending on the number of layers and are distinguished as small unilamellar vesicles (SUV) or large multilamellar vesicles (LMV) [122, 123].

Liposomes are largely related to lipid characteristics such as charge, size, saturation and length of the acyl chains and the characteristics of the encapsulated molecule itself (molecular mass, solubility, charge, hydrophobicity, etc). Other considerations are the method of vesicle production, drug encapsulation methodology, and the addition of molecules that are able to crosslink the membrane [158]. Effective liposomal encapsulation of small-molecular-mass molecules (most of the used therapeutic agents belong to this class of molecules) can be performed employing two different loading procedures. The first is passive loading, which is adding active substances into a liposome formulation during the preparation of the vesicle. The other is active loading where the active substance is added to preformed liposomes [159].

In terms of membrane permeability the size of the vesicle is very important. The most stable size of liposomes are between 100 and 200 nm in diameter and they display better drug retention than larger liposomes of the same composition. Saturation of the lipids influence membrane integrity, the release kinetics throughout the membranes increase with the degree of unsaturation of the acyl chains [160]. Cholesterol has also been found to increase the packing density of liposomes and to decrease the bilayer permeability [160, 161].

Liposomes encapsulate a part of the solvent, in which they freely diffuse (float) into their interior [145, 146]. Upon interaction with water, polar lipids self-assemble and form self-organized colloidal particles. A cross-section of a liposome (Fig 2.9) shows the hydrophilic heads of the amphipilic vesicle orienting towards the water compartment while the lipophilic tails orient away from the water towards the center of the vesicle, thus forming a bilayer. Consequently, water soluble compounds aggregate in the lipid section. Exclusively liposomes can encapsulate both hydrophilic and lipophilic materials [158].

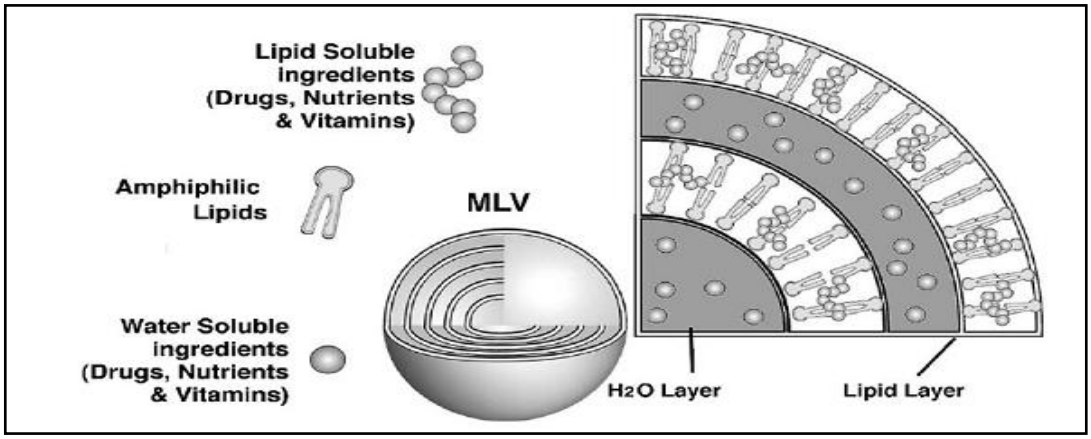

Figure 2.9. Cross-section of a liposome [153]

Liposomes are similar to the lipid membrane part of cells. Several biological processes in living organisms depend on the action of small uni-lammelar liposomes. Typical compositions involved phosphatidyl cholines, phosphatidyl ethanolamines, frequently containing negatively charged lipids such as phosphatidyl serine and phosphatidyl inositol. In addition, ceramides such as sphingomyelin, sterols (cholesterol, ergosterol, sitosterol, etc.) are also incorporated [162]. With respect to the number of lamellae and size of liposomes, small unilamellar vesicles (SUV) have a size < 0.1 μm, large unilamellar vesicles (LUV) have a size range of 0.1-1 μm, and large multilamellar vesicles can be up to 500 μm in diameter and contain hundreds of concentric bilayers [163]. Liposomes are composed of relatively biocompatible and biodegradable material, and they consist of an aqueous volume entrapped by one or more bilayers of natural and/or synthetic lipids. (Figure 2.9) [163].

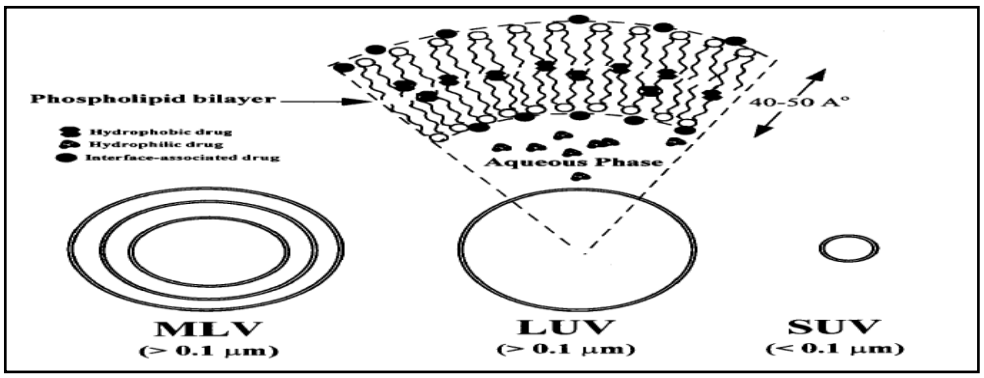

Figure 2.10. Type of liposomes depending on size and number of lamellae [167]

2.5.2. Liposome Applications

Liposome vesicles are particularly used as a model for drug delivery carriers in basic research, due to their composition and structure. Liposomes are used in applications ranging from drug and gene delivery to diagnostics, cosmetics, long-lasting immune contraception and the food industry, due to their biocompatibility, biodegradability and absence of toxicity [164].

2.5.3. Liposomes as Drug Delivery Carriers to Microbial Infections

Nanoencapsulation of bioactive compounds characterize a viable and efficient approach to increasing physical stability of EO's active substances [165]. While microcapsules may assure excellent protection for EOs against degradation or evaporation, they do not generally respond to antimicrobial activity against microorganisms; whereas, nanometric size delivery systems improve cellular fusion mechanisms. As a consequence, excellent antimicrobial activity can be observed against microbial pathogens [142]. This has been shown previously with the encapsulation of eugenol and carvacrol into nanometric surfactant micelles resulting in enhanced antimicrobial activity [158].

One of the most important properties of the oral mucosa is its selective permeability. This feature enables its utilization for systemic and local transfer of some drugs. The basic goal for liposomal vehicles carrying antimicrobial EO's is that active substance should be able to reach the target area in the right time, in the right concentration and at the right ratio [166]. Liposomal formulations have been used both to enhance absorption and to regulate release of incorporated drugs, thus localizing the effect of the drugs [167, 168]. Liposomes incorporating EO's have been shown as an appropriate instrument for successful application of local drug delivery systems in the oral cavity [160].

2.5.4. Antimicrobial Activity of EO incorporated Liposomes

The antimicrobial activity of many EOs is known to be due to the phenolic constituents of the EO [116]. Unfortunately, most natural compounds are biologically instable, poorly soluble in water and they distribute poorly to target sites. Currently, novel methods have

been introduced in order to improve their stability and their bioavailability, amongst which is the use of liposomal encapsulation [164].

Liposomes are useful drug delivery carriers for antimicrobial therapies owing to the potential to carry and deliver the entrapped EO across the cell membrane. Therefore, liposomal drug delivery carriers have been extensively studied as a carrier system which can increase the activity and safety of many drugs [77].

In the literature, liposomal incorporation of several plant EO and their in vitro antimicrobial activities were studied [77, 169, 170].

The effect of liposomal inclusion on the in vitro antiherpetic activity of *Artemisia arborescens L*. EO was investigated. In order to study the influence of liposome vesicle structure and composition on the antiviral activity of the vesicle-incorporated oil, Multilamellar (MLV) and Unilamellar (SUV) positively charged liposomes were prepared by the thin film hydration method and sonication. Also, liposomes included hydrogenated (P90H) and non-hydrogenated (P90) soy phosphatidylcholine. Then, antiviral activity was tested against *Herpes simplex* virus type-1 (HSV-1) by a quantitative tetrazolium-based colorimetric method. Results showed that *Artemisia* EO was successfully incorporated into the prepared liposomes. Antiviral assay results showed that that the liposomal incorporation of *Artemisia arbosencens* EO increased its in vitro antiherpetic activity especially when the liposomal vesicles were made with P90H. Conversely, no significant antiviral activity was observed between free and SUV-incorporated oil [77].

Another study demonstrated that liposomal incorporation of carvacrol and thymol isolated from EO of *Origanum dictamnus L*. had antimicrobial activity.. The chemical composition of the EO from *O. dictamnus* was determined by GC-MS. Then, carvacrol, thymol, p-cymene and γ- terpinen were identified as major constituents and isolated. These components were successfully encapsulated into phosphatidylcholine- based liposomes and then the possible enhancement of the antimicrobial activity was determined against four Gram positive and four Gram negative bacteria and three human pathogenic fungi, in addition to the food borne pathogen. All tested components presented antimicrobial activity after the encapsulation [169].

Incorporation of *Anethum graveolens* EO into liposomes was also studied in the literature. The influence of liposomes composition, size and lamellarity on the entrapment efficiency of EO was studied. For this purpose, MLV and SUV liposomes were prepared by the thin film hydration methods. The stability of liposome vesicles and vesicle dispersions were characterized for their oil content and average size distribution. Results showed the incorporation of *Anethum graveolens* EO in liposomes in good amounts when suitable formulation are used. The EO incorporated liposomes and its composition was approximately stable over one year, size distribution demonstrated also slight modification, especially SUV [170].

Also, in the literature interactions between cationic loaded liposomes and bacteria were investigated [171]. Liposomes were used as carriers for antimicrobial and anticancer agents in this study [171]. Small unilamellar DODAB vesicles (SUV) were prepared by ultrasonic dispersion. Susceptibilities of different bacteria species towards DODAB cationic vesicles were determined. Also, interaction between cationic liposomes and bacteria, the physical chemistry of the bactericidal action was determined [171]. Results showed that negatively charged cells were 100 % viable whereas positively charged cells did not survive. The results demonstrated a clear correlation between simple adsorption of entire vesicles generating a positive charge on the cell surfaces and cell death [171].

3. AIM OF THE PROJECT

The aim of this study was to assess the possibility of incorporating EO of *S. hortensis L.* into two novel liposome formulations prepared according to the Bangham method. Furthermore, to characterize these liposomes (mean size, zeta potential, poly dispersitive index using different microscopic techniques, (PLM and AFM) and evaluate their antimicrobial activity against oral pathogens using agar well diffusion assay.

4. MATERIALS

4.1. GROWTH MEDIA

Brain Heart Broth (BHB) (Salubrus, Massachusettes, USA), Fastidious Anaerobe Broth (FAB) (LabM, UK), Fastidious Anaerobe Agar (FAA)(LabM, UK) and Brain Heart Infusion (BHI) 5 % Sheep Blood Agar (Salubris, Massachusettes, USA) were employed for the cultivation of oral bacteria and Saboaraud Dextrose Agar (SDA) (Merck, New Jersey, USA) and Saboaraud Dextrose Broth (SDB) (Merck, New Jersey, USA) were used for yeast. All media were prepared according to the manufacturer's instructions.

4.2. CHEMICALS AND SOLUTIONS

4.2.1. Chemicals for Essential Oil Extraction

Anhydrous sodium sulphate powder (Sigma, Germany) and xylene (Sigma, Germany) were used for essential oil extraction.

4.2.2. Chemicals for Preparations of Liposomes

Phospholipon P85G (PL85G) (Lipoid, Germany), stearylamine (SA) (Sigma, Germany), cholesterol (CH) (Merck, Germany), chloroform (0.1%) (Sigma, Germany), ethanol (Sigma, Germany) were used for preparation of liposomes.

4.2.3. Chemicals and Solutions for Antimicrobial Tests

4.2.3.1. 1X Phosphate Buffered Saline (PBS) Solution (pH 7.4)

For the preparation of 1X PBS solution at pH 7.4 8.18 g of NaCl (Merck, Germany), 0.186 g of KCl (Appli.Chem, Germany), 1.136 g of Na_2HPO_4 (AppliChem, Germany) and 0.272 g of KH_2PO_4 (AppliChem, Germany) were dissolved in 800 ml of sterile distilled water. After adjusting the pH of the solution to 7.4, the final volume was completed to 1 liter. The solution was, then autoclaved.

4.2.3.2. Mc. Farland No: 0.5 Standard Solution

To prepare the standard solution, first of all stock solutions of 1 % barium chloride ($BaCl_2$) and 1 % sulfuric acid (H_2SO_4) were prepared as follows: 10 ml of 1 % $BaCl_2$ stock solution was prepared by dissolving 244 mg of $BaCl_2$ powder (AppliChem, Germany) in 10 ml of sterile distilled water. 100 ml of 1 % H_2SO_4 stock solution was prepared by taking 1.05 ml of H_2SO_4 (95-97 %) (Sigma, Germany) and adding it to 99 ml of distilled water.

0.5 McFarland standard was prepared by mixing 0.05 ml of 1.175 % Barium Chloride dehydrate ($BaCl_2$.2HO) with 9.95 ml of 1 % Sulfuric acid. The absorbance of this mixture was then measured at 600 nm (OD 600nm = 0.132) by microplate reader (Thermo Lab Systems, Germany).

4.2.3.3. Brain Heart Broth With 0.1 % Tween 80

Tween 80 is a nonionic emulsifier which facilitates the mixing of immiscible broth medium and essential oil. Brain heart broth (BHB) was prepared and sterilized. 50 µl of BHB brain heart broth was taken and discarded from 50 ml of BHB medium. 50 µl of Tween 80 (Sigma, Germany) was added to BHB to make a final concentration of Tween 80 0.1 % (Sigma, USA) in 50 ml of BHB.

4.2.3.4. Brain Heart Broth With 1 % Sucrose

Stock solution of 10 % sucrose solution was prepared by weighing 20 g of sucrose (Bio.Basic, Canada) and dissolving it in 200 ml of distilled water. BHB medium with 1 % sucrose was prepared as follows; 50 ml of 10 % sucrose solution was added into 450 ml of BHB, while passing the sucrose through 0.25 µm filters (Whatman, USA).

4.2.3.5. Brain Heart Broth With 0.1 % Tween 80 and 1 % Sucrose

50 ml of Brain Heart broth with 1 % sucrose was prepared and placed in a sterile falcon tube. Then 50 µl was discarded and replaced with 50 µl of Tween 80. This resulted in BHB medium with 0.1 % Tween 80 and 1 % sucrose.

4.2.3.6. Methanol

Methanol (≥99.6%, Sigma, USA) was used as a solvent. *S. hortensis* L. essential oil was dissolved in methanol and then diluted to different concentrations.

4.2.3.7. Plant Material

The aerial parts (flowers, leaves, stems, twigs, and roots) of *S. hortensis* L. herb were collected from the province of Erzurum at the end of the summer in August 2010. All the plant samples were stored in a dark and cool place until use.

4.2.3.8. Laboratory Equipments

Shaker (BS-T, Sartorius, Aubagne, France), Rotator (SB3, Stuart, Staffordshire, USA), Vacuum machine (GmbH, Ilmvac, Ilmenau, Germany), spectrophotometer (Mutiskan Spectrum, Thermo, Massachusetts, USA), Anaerobic workstation, (Don Whitley Scientific, UK), 50 ml falcon centrifuge (J-25 I, Beckman, Brea, USA), microcentrifuge (Sigma-Aldrich, Taufkirchen, Germany), autoclave (Hirayama, Saitama, Japan), laminar flow(HFsafe-1200, Heal Force, Shanghai, China), incubators (Memmert, ShellaB, Forest Grove, USA), and Malvern Zetasizer instruments Nano ZS (Worcestershire, United Kingdom), GC (Thermo Fisher Scientific, USA) Vortex (Heidolph,Germany), Clevenger apparatus (Inter Lab, Turkey), Atomic force microscopy (AFM) (Shimadzu, Japan), Polarized Light Microscopy (PLM) (Nikon, USA), Lyophilizator (Christ, Osterode, Germany), Vacuum incubator (Thermo Scientific, USA), Rotovapor, (Heidolph , Germany), Sonicator (Sonorex,Germany), Waterbath (OLS200, Grant, Cambridgeshire, England), Lab Scale (Ohous, UK), Extruder (Kanotz, USA), 20^{o}C Refrigerator (Beko, Turkey), Polycarbonate filter (Whatman, USA), turbidimetry (BIOLOG, Hayward CA) were used.

4.2.3.9. Laboratory Consumables

Elisa plates, pipettes, micropipettes, pipette tips, petri plates, plastic and glass erlenmeyers, beakers, eppendorfs, Bunsen burner, falcon tubes, pestle and mortar, paraffin, masks, napkins, scissors, standard ruler and gloves were used in different parts of the experiment.

5. METHODS

5.1. EXTRACTION OF *S. HORTENSIS L* ESSENTIAL OIL (EO) BY HYDRODISTILLATION

Figure 5.1. Clevenger apparatus for essential oil extraction

Leaves and flowers of *S.hortensis* L. were collected from the Eastern Anatolian region of Turkey in August 2010. Plant samples (aerial parts) were air-dried in a dark place at room temperature for 10 days. Following drying process, plant samples were stored for 1,5 months at room temperature. Then, the dried plant samples were transferred from Erzurum to Istanbul in order to use for the experimental analysis. Plants (Dried plant samples (3kg)) were crushed by pestle and mortar and a total of 120 g was placed into four 500 ml round bottom flasks (30g each) and 400 ml of sterile distilled water added to each flask. Plant parts including leaves, flowers, branches and roots were processed together. Plants were then subjected to hydrodistillation using Clevenger apparatus (Interlab, Turkey) for 3 h (Fig 5.1).

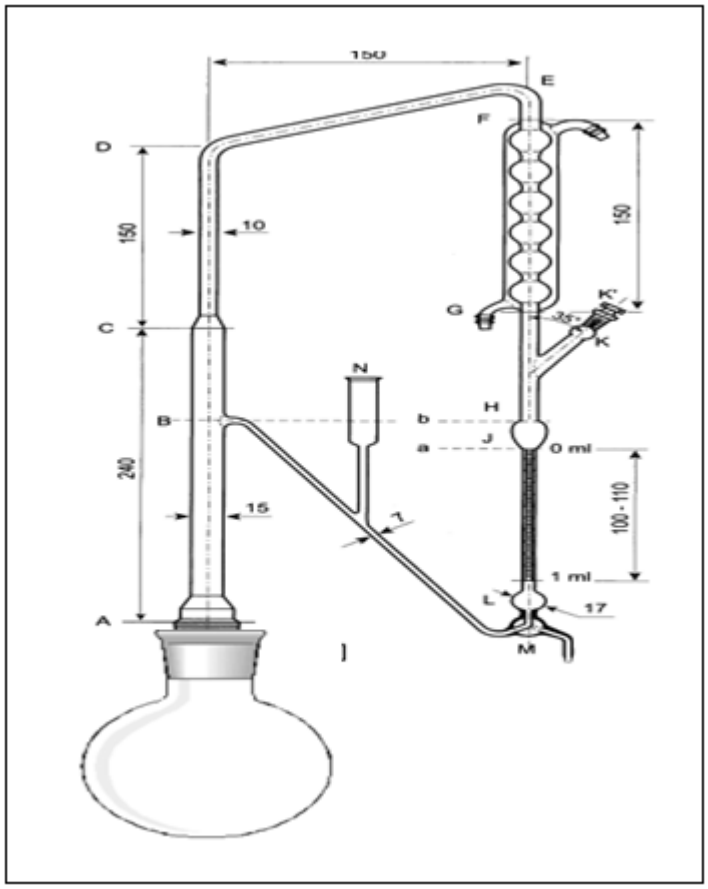

Figure 5.2. Schematic diagram of Clevenger apparatus (dimensions are shown in millimeters) [172, 173]

The mechanism of the Clevenger apparatus is shown in Fig 5.2. The plant sample was placed into the round bottom flask (I part). Distilled water was poured into the clevenger apparatus through the funnel 'N' until the water became equal at 'B' and 'H' points. 0.5 ml of xylene was added to the apparatus from the tube 'K' to entrap the extracted essential oil. When xylene is added, it flows on the water surface and during distillation, the little amount of extracted EO was collected in xylene After adding xylene, the 'K' part was closed with aluminum foil. Hydro-distillation was carried out for 3 hours in order to achieve maximum recovery of EO [138]. As soon as the distillation process was completed, essential oil (EO) was collected from the 'K2 tube by means of a glass pippet. Anhydrous sodium sulphate was then added to the mixture of essential oil, xylene, and water (H-J). Anhydrous sodium sulphate absorbed the residual water and xylene from the essential oil. Xylene also increases the yield of EO extract. EOs were then collected in glass vials, which were sealed with aluminum foil and stored in -20 $^{\circ}$C to be used later.

5.2. CALCULATION OF EO DENSITY AND YIELD

The relative density of the essential oil was determined using the gravimetric method [101] as follows: Mass of 10 ml distilled water was determined (m_3) using Lab Scale (Ohaus, UK). Then, 1 ml of distilled water was discarded, and mass of the remaining 9 ml was determined (m_1). 1ml essential oil was added into 9 ml sterile distilled water. Mass of this water and oil mixture (10 mL) was also determined (m_2). The relative density of the essential oil was then calculated according to the equation [101]:

$$d = \frac{m_2(mg) - m_1(mg)}{m_3(mg) - m_1(mg)}$$

Table 5.1. Explanation of Equation for Calculation of Essential Oil Density

d	Relative density of essential oil
m_1	Mass of 9 ml distilled water (mg)
m_2	Mass of 10 ml essential oil and distilled water mixture (mg)
m_3	Mass of 10 ml distilled water (mg)

Extraction yield was calculated as the of the weight of the crude extract to that of the raw material (120g) as follows :

$$\text{Extraction yield } (\%) = \frac{\text{weight of the essential oil extract (mg)}}{\text{weight of the original sample (mg)}} \times 100$$

5.3. SAMPLE PREPARATION FOR GC

Two hundred (200) µl *S. hortensis* L. extracted EO extract was dissolved in 800 µl hexane (≥ 85 %) (Sigma, USA) in order to dilute the EO. Following dilution with hexane, 200 µl of the sample solution was used for gas chromatography analysis.

5.4. GAS CHROMOTOGRAPHY ANALYSIS

A Thermo ISQ (Thermo Fisher Scientific, USA) GC-MS QP5050A system with CP-sil 5CB column (25mx0.25mm i.d.0.4 µ L film thickness) was used with helium as carrier gas. The GC oven temperature was kept at 60 °C and programmed to 260 °C at a rate of 5 °C/min, and was then kept constant at 260°C for 40 minutes. The split flow was adjusted to 50 ml/min. The injector temperature was at 250°C. In the mass spectrometry (MS) analysis of an electron impact source with the ionization energy set at 70 eV was used. A total ion current (TIC) chromatogram was produced by scanning between m/z 30 and 425. Identification of EO components were achieved from the TIC chromatogram, the mass spectra of the EO components were automatically searched using the in-house WILEY7 Library of the Essential Oil Constituents of the equipment [174, 175] by comparison of the data base including mass spectra of fragment of those chemicals [176, 177, 178]. Peaks were identified using GC/MS. The peaks were detected Mass spectral Data base having mass spectra of the chemicals [179].

5.5. PREPARATION OF LIPOSOME FORMULATIONS

Unloaded liposomes were prepared according to the thin film hydration method [156]. There are different liposome preparation method [180]. Liposomes containing stearylamine, cholesterol and phospholipids in varying amounts (Table 5.1) were dissolved in 40 ml of chloroform solvent (≥99.8% (chloroform + ethanol)) (Sigma, USA) containing 0.1 % ethanol in a 50 ml round bottomed flask [156]. All these ratios and substances were chosen according to thin film hydration method [156]. The solvent mixture was evaporated under reduced pressure (≤ 20 Bar nitrogen pressure) at room temperature using a rotary evaporator (Heidolph, Germany) to obtain a thin film. The flask was then incubated using the vacuum incubator (Thermo Scientific, USA) at 25°C for 24h. The thin film was hydrated with 40 ml sterile distilled water at room temperature. The film was then sonicated using a sonicator (Soniprep 150, MSE, Crowley) for 15 min. Then the unloaded liposomes were extruded by way of an extruder (LF-50) (Kanotz, USA) using a polycarbonate filter (200nm and 400nm; Whatman, Canada) in order to obtain a homogeneous and relatively smaller size dispersion under a nitrogen stream (Havas, Turkey). The extruder was connected to a nitrogen gas tube (Havas, Turkey). Finally, the

liposomes were freeze dried at – 80°C using a freeze drier (Christ, Osterode, Germany) and stored at -20°C, until further use.

Table 5.2. Different Liposome Formulations

	PHOSPHOLIPID (Type & Molarity)	**STEARLYAMINE Molarity(M)**		**CHOLESTEROL Molarity(M)**		**ESSENTIAL OIL**

L2	Ab	27.50	1.075	Ab	6.2	911

UL:Unloaded liposome
L: Loaded liposome
Ab: Absent (Not added)
M. Molarity

5.6. INCORPORATION OF EO INTO LIPOSOMES

Following preparation of unloaded liposomes (UL) by the thin film technique (Table 5.1) freeze dried liposomes were hydrated by dispersing in 5ml of sterile distilled water. One ml of the unloaded liposome dispersion was then placed in a sterile glass tube and an equal amount of EO was incorporated into the dispersed (hydrated) liposome by active loading. The final liposomal dispersion of EO was thoroughly vortexed until a milky appearance was obtained. Finally, liposomes (vesicles) containing EO were stored at 4°C until reuse.

5.7. CHARACTERIZATION STUDIES OF LIPOSOMES: MEAN PARTICLE SIZE, SIZE DISTRIBUTION, POLYDISPERSITY INDEX AND ZETA POTENTIAL

The EO loaded liposomes were characterized by way of zeta size determinations and zeta potential measurements, as they were extruded, in order to obtain homogenous particle size distribution. Small unilammelar vesicles always provide better properties for liposomal applications. The particle size and zeta potential of loaded liposomes were determined for both loaded and unloaded liposomes by Dynamic Light Scattering (DLS) (MALVERN,

USA). Mean particle sizes went in line with intensity-based data (DTS, Nano Application, MALVERN, USA). The mean particle size and size distribution together with poly-dispersity index data were obtained by DLS software and all data was statistically evaluated by Minitab 16 Statistical Software (Inova, UK). The intensity mean diameter of loaded liposomes size distribution was determined by photon correlation spectroscopy using Zeta sizer (Malvern instruments Ltd., USA) at 25°C with 90° scattering angle and statistically evaluated by Minitab 16 Statistical Software (Inova, UK). All experiments were carried out intriplicate.

5.8. MORPHOLOGICAL CHARACTERIZATION OF LIPOSOMES

5.8.1. Polarized Light Microscopy (PLM) Studies of Liposomes

Figure 5.3. Polarized light microscope

Optical and light polarized micrographs were obtained by an optical microscope (Zeiss Axioplan 1, USA), at 25°C (Fig 5.3). A drop of hydrated liposome sample was placed onto a sterile glass slide and covered with a coverslip. Morphological observation were made using polarized light at 100 X magnification of the microscope using immersion oil, in order to confirm vesicular formation and determine vesicle type (Multilamellar vesicles (MLV), Small unilamellar vesicles (SUV), etc). Images were obtained using a bright-field with either the monochrome or coloured camera as appropriate. Axiovision software (Carl Zeiss Microscopy, Germany) was employed for image capture.

5.8.2. Atomic Force Microscopy (AFM) of Liposomes

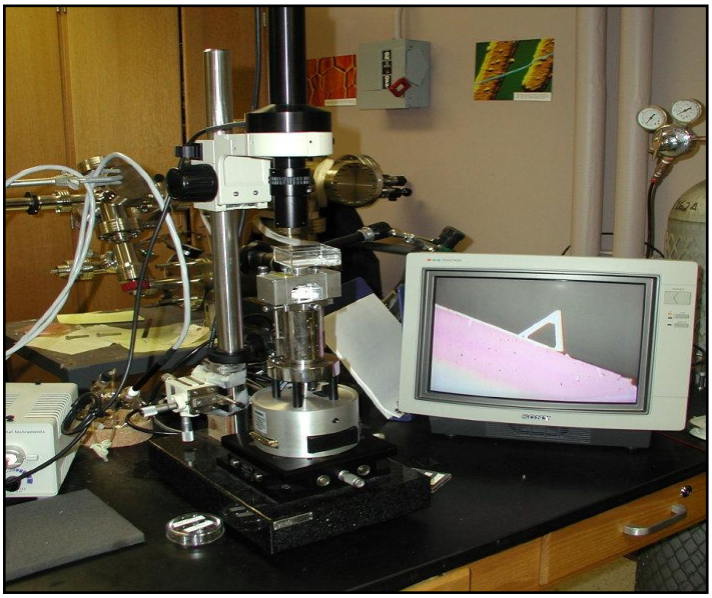

Figure 5.4. Atomic force microscope

AFM (Park Systems XE-100, Korea), was used to evaluate the physical characteristics (morphological and metrology) of the prepared liposomal formulations. Five µl of each liposome formulation was dropped onto individual glass slides and fixed by drying at room temperature. The AFM images of samples were obtained in noncontact mode at room temperature. Silicon nitride tips (Nano and More, Germany) were used with varying resonance frequencies (0.75, 6.5, 25, 35, 135, 200, 680, 1000, 1400 kHZ) at a linear scanning rate of 0.75 Hz. All measurements were taken using the Atomic Force Microscopy shown in Fig.5.4

5.9. TESTED MICROORGANISMS

The antimicrobial activity of *S.hortensis* L. EO loaded liposomes were tested against several oral microorganisms. Test microorganisms were selected based on their known association with oral infections. Species and strains studied were: *Aggregatibacter actinomycetemcomitans* FDC Y4, *Prevotella intermedia* ATCC 25611, *Porphyromonas gingivalis* ATCC 33277 and *Fusobacterium nucleatum* ATCC 25586 which were kindly donated by Dr. Philip Bird, Queensland University, Australia. *Streptococcus mutans* and

Candida albicans were supplied from -80°C culture collection of Yeditepe University, Genetic and Bioengineering Department.

Test microorganisms were activated from -80°C stock culture by subculturing on Saboaraud Dextrose Agar (SDA) (Merck, New Jersey, USA) for *C. albicans* and both Brain Heart Broth (BHB) (Salubrus, Massachusettes, USA) and 5 % Brain Heart Infusion Sheep Blood Agar (Salubris, Massachusettes, USA) for all other test microorganisms. Yeast and bacteria were incubated aerobically at 37°C for 48 h and anaerobically at 37°C for 48-72 h in an anaerobic workstation (Don Whitley scientific, UK) containing10 % CO_2, 10 % H_2, and 80 % N_2 gas mixture (Havas, Turkey) respectively.

5.10. ANTI-MICROBIAL ACTIVITY TESTING

5.10.1. Agar Well Diffusion Assay

The antimicrobial activity of *S.hortensis L.* EO loaded liposomes (L1 and L2) were tested against six oral microorganisms and a mixed combined culture, by way of the agar well diffusion assay [168, 185]. Following 24 h aerobic incubation for *C. albicans* and 48 h for *S. mutans* at room temperature and 48 h anaerobic incubation for *F. nucleatum*, *A. actinomycetemcomitans*, *P. gingivalis* and *P. intermedia* at 37°C, a loopful of bacteria was inoculated into 2 ml of 1X phosphate buffered saline solution (pH 7.4) (Gibco, USA) and vortexed to obtain a homogenous suspension. A stock solution was prepared by adjusting the bacterial suspension to McFarland No. 0.5 ($2x10^8$cfu/ml) standard solution using a turbidity meter (BIOLOG, Hayward CA). A mixed culture was obtained by adding 100 µl of each bacterial stock solution together and adjusting the turbidity with PBS to reach a final suspension of $2x10^8$cfu/ml.

One hundred µl of the stock solution was inoculated onto the appropriate media with 15 µl of the (100 % concentration of EO with a density of 911 mg/ml) of free EO, unloaded liposomes (UL1 and UL2) and loaded liposomes (L1 and L2). Due to the hydrophobic nature of the free EO, 15 µl of 10 % (v/v) methanol solution (≥99.6%, Sigma, USA) was used as an emulsifier for free EO in order to increase its dissolving capacity. Furthermore, 0.1 % Tween 80 was added to loaded liposomes as an emulsifier in order to increase the

liposome surface zeta potential, stability of the liposome and penetration rate across the biological membrane due to its surfactant structure [168]. Negative and positive controls were used on each plate. Negative controls included sterile distilled water, unloaded liposomes and 10 % methanol. Positive controls were free EO and chlorhexidine gluconate (CHX) (0.12 mg/ml), (Kloroben, Drogsan, Turkey). A schematic diagram of the experimental design is shown in Figure 5.6.

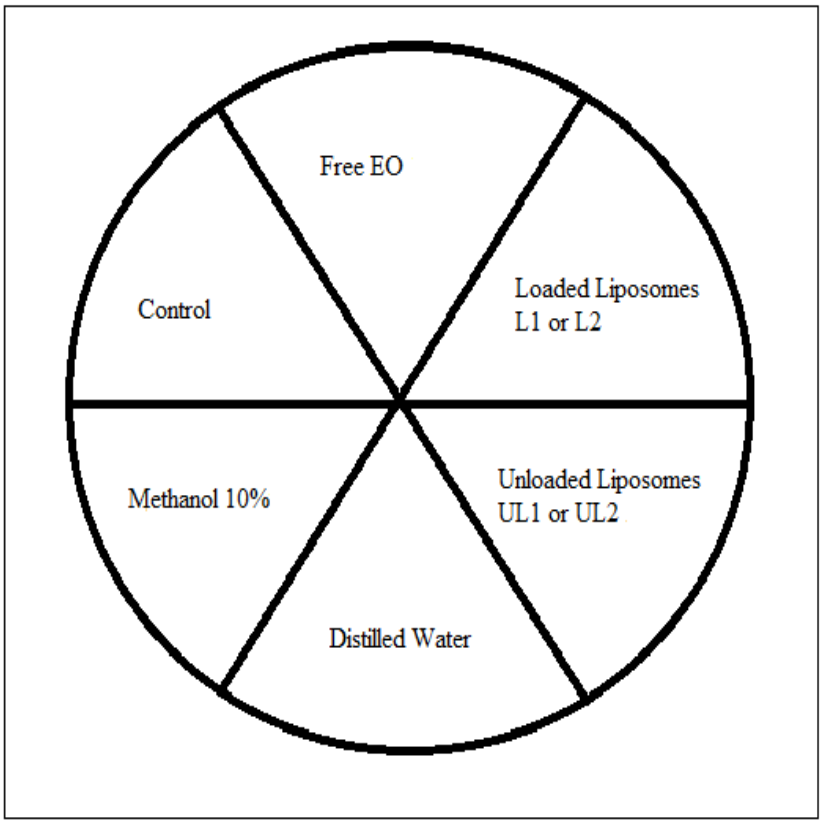

Figure 5.6. Schematic diagram of agar well diffusion assay
Free EO at 100% concentration, liposomes (L1 and L2), Negative controls: sterile distilled water, unloaded liposomes (UL1 and UL2) and 10% methanol. Positive Control: free EO and Chlorhexidine gluconate (CHX) (0.12 % v/v)

Plates were incubated at appropriate temperatures and tested against selected oral microorganisms upto 120 hrs. This time was chosen according to bacterial growth requirements (*e.g. P. gingivalis* 72 h) and the slow releasing nature of liposomes.

Following incubation, inhibition zones were measured including the diameter of wells and recorded over a period of up to 5 days to test for sustained release from the loaded liposomes.

5.11. STATISTICAL ANALYSIS

Statistical analysis was conducted with the statistical programme; Minitab 16 Statistical Software (Inova, UK). All experiments were performed in triplicate. Statistical significance was determined using one-way analysis of variance at 95 % confidence level. Descriptive statistics, including the mean ± standard deviation (SD) were calculated. To determine whether the mean were statistically different from each other a Tukey's pair wise comparison test was used at the chosen level of significance at $P < 0.05$. The statistical significance of killing and inhibition of bacterial growth were determined. Comparison of results between groups beside Anova, for multiple comparisons used Dunnet's multiple comparison tests. P values of 0.05 were considered significantly different.

6. RESULTS

In this study, the preparation, incorporation, characterization and antimicrobial effect of two liposomes incorporating *S.hortensis* L EO were investigated.

6.1. EXTRACTION OF ESSENTIAL OIL BY HYDRODISTILLATION

Distillation of the aerial parts of *S.hortensis* L. gave a volatile, yellow EO with a strong odor. The relative density of the EO extracted by the hydrodistillation method was calculated by the gravimetric method and found as 911 at room temperature [101]. Extraction yield was calculated as 7.5 % (w/w).

6.2. CHEMICAL COMPOSITION OF ESSENTIAL OIL (GC-MS)

GC-MS data shows the identification of the components listed according to their elution on the 5CB-column. In total, 52 components were identified (Table 6.1). GC-MS analysis revealed that the most abundant components were notably carvacrol (41.65 %), thymol (10.29 %), and monoterpenic hydrocarbons, p-cymene (16.16 %), α-Terpinene (4.91 %) as phenolic monoterpene, and others such as γ-Terpinene (27.44 %), β-caryophyllene (2.94 %). Moreover, Germacrene-D (0.08 %), Ledene (0.57 %), α-Cadinene (0.94 %), p-Cymen-2-ol (0.19 %), Junipene (0.03 %), Sabinene (0.28 %) and α-Phellandrene (0.49 %) were other components found in minimal concentrations.

6.3. PREPARATION AND CHARACTERIZATION OF LIPOSOMES

Two unloaded liposomes (UL1 and UL2) were prepared at different ratios of phospholipid 85 G (PL85G), cholesterol (CH) and stearylamine (SA) (Table 6.2). The liposomes were then loaded (L1 and L2) with extracted *S. hortensis* EO.

Results of the characterization studies (molar ratio, size, size distribution, zeta potential, poly dispersitive index (PDI) and appearance) of unloaded liposomes (UL1, UL2) and loaded liposomes (L1, L2) are shown in Table 6.2.

Table 6.2. Liposome formulations, their compositions, measurements for particle size, zeta potential and PDI values

Code	Composition	Molar Ratio	Average diameter (nm)	Zeta potential (mV)	PDI	Observations
UL1	PL 85 G:SA:CH	7:1:2	146.9 ± 2.8	34.8 ± 2.2	0.39 ± 0.01	Milky dispersion
UL2	PL 85G:SA:CH	10:1:4	147.8 ± 2.1	46. 5 ± 1.8	0.30 ± 0.01	Milky dispersion
L1	PL85 G:SA:CH +EO	7:1:2	412.5 ± 13.9	-36.7 ± 0.7	0.41 ± 0.02	Milky dispersion
L2	PL 85G:SA:CH +EO	10:1:4	2171 ± 151.0	-29.9 ± 1.7	0.16 ±0.07	Milky dispersion

Values represent the mean ±standard deviation of three experiments
UL: Unloaded liposomes
L: Loaded liposomes
PDI: Poly dispersive index
CH: Cholesterol
SA: Stearylamine
PL85 G: Phospholipid 85 G

The zeta potentials for UL1 and UL2 formulations were cationic (positive) 34.8 ± 2.2 mV and 46.5 ± 1.8 mV, respectively. Following loading with EO, it was observed that the zeta potential of the vesicles became anionic -36.7± 0.7 mV for L1 and -29.9 ± 1.7 for L2 loaded liposomes. Statistical analysis comparing the zeta potential of liposomes UL1 with UL2 and loaded liposomes L1 with L2 revealed a significant difference ($p<0.05$).

All liposome vesicles were extruded using polycarbonate filters (200nm and 400nm) to obtain homogeneous and relatively smaller size dispersion under a nitrogen stream. The obtained particle sizes were between 146.9 ± 2.8 - 147.8 ± 2.11 nm for unloaded liposomes (UL1 and UL2) while the diameter size of loaded liposomes were observed as L1: 412.5 ± 13.93 nm and L2: 2171 ± 151.0 nm, respectively.

Even the mean particle size of unloaded liposomes, UL1 (146.9 ± 2.8 nm) and UL2 (147.8 ± 2.11 nm) were not significantly different ($p>0.05$), when they loaded with EO their particle size increased to 412.5 ± 3.93 nm and 2171 ± 151.0 nm for L1 and L2, respectively (Figure 6.1 and 6.2). The data showed that EO loaded liposomes, L1 and L2, had significantly different mean particle sizes ($p<0.05$).

Furthermore, following loading with EO, PDI values for both L1 and L2 loaded liposome formulations according to DLS analysis were 0.41 ± 0.02 and 0.16 ±0.07, respectively. However, the particle size of L2 (2171 ± 151.0 nm) was seen to be much larger than that of L1 (412.5 ± 13.93 nm). The observed larger size was due to the aggregation of liposomes in the L2 formulation. According to the literature, a small PDI value (lower than 0.1) indicates a homogenous population of particles, while a PI above 0.3 indicates a high degree of heterogeneity [167, 168].

The PDI values of the UL1 and UL2 unloaded liposomes were not significantly different ($p<0.05$), upon loading with EO, L1 and L2 liposomes displayed significantly different PDI values ($p> 0.05$).

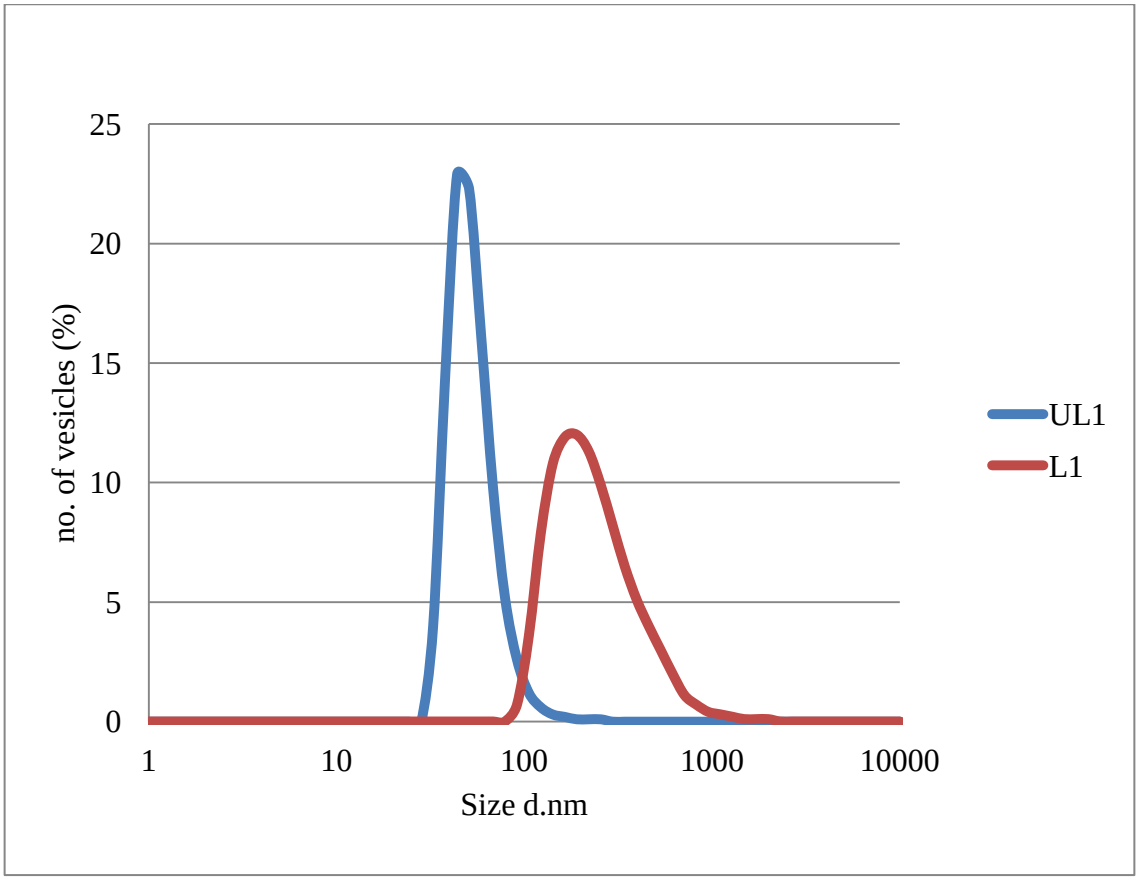

Figure 6.1. DLS Analysis of unloaded (UL1) and Loaded Liposomes (L1)

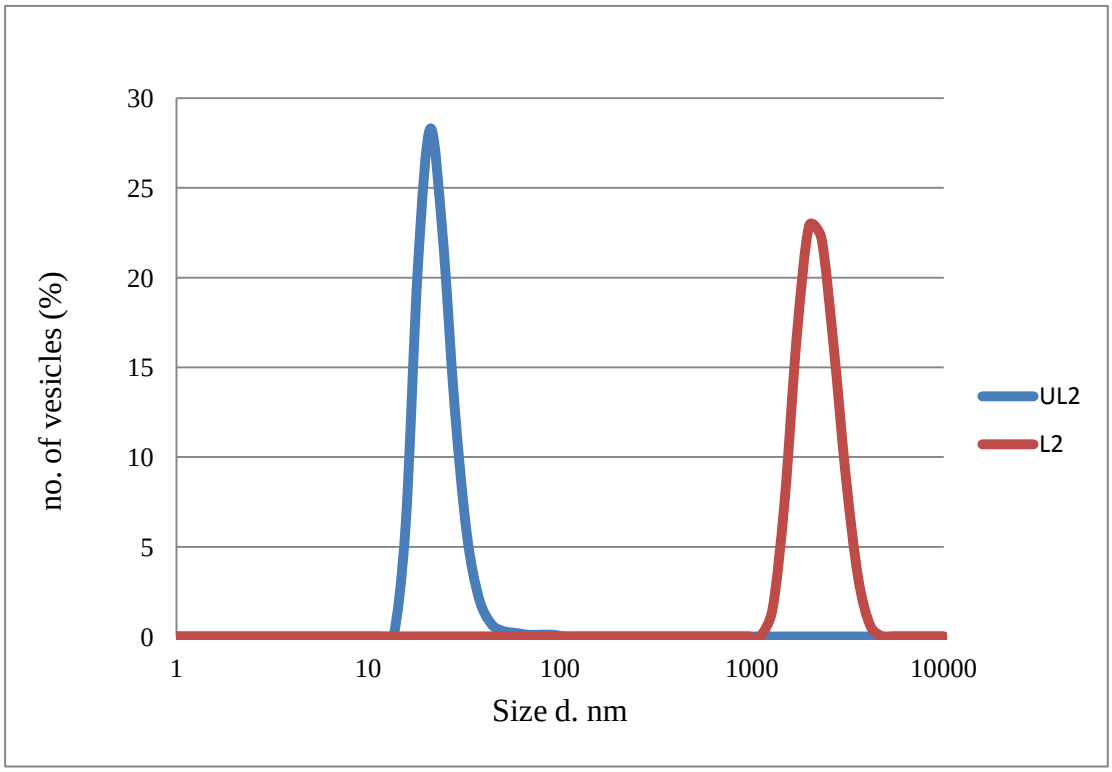

Figure 6.2. DLS Analysis of unloaded (UL2) and Loaded Liposomes (L2)

6.4. MORPHOLOGICAL CHARACTERIZATION OF LIPOSOMES

Morphological characterization of unloaded liposomes (UL1, UL2) and the loaded liposomes (L1 and L2) were examined by polarized light microscopy (PLM), and atomic force microscopy (AFM).

6.4.1. Polarized Light Microscopy

The images of unloaded and loaded liposomes are shown in Figures 6.3.a and 6.3.b, respectively. Images of polarized light microscopy confirmed that the EO was successfully loaded into the vesicles and as expected loading with EO increased the size of liposomes.

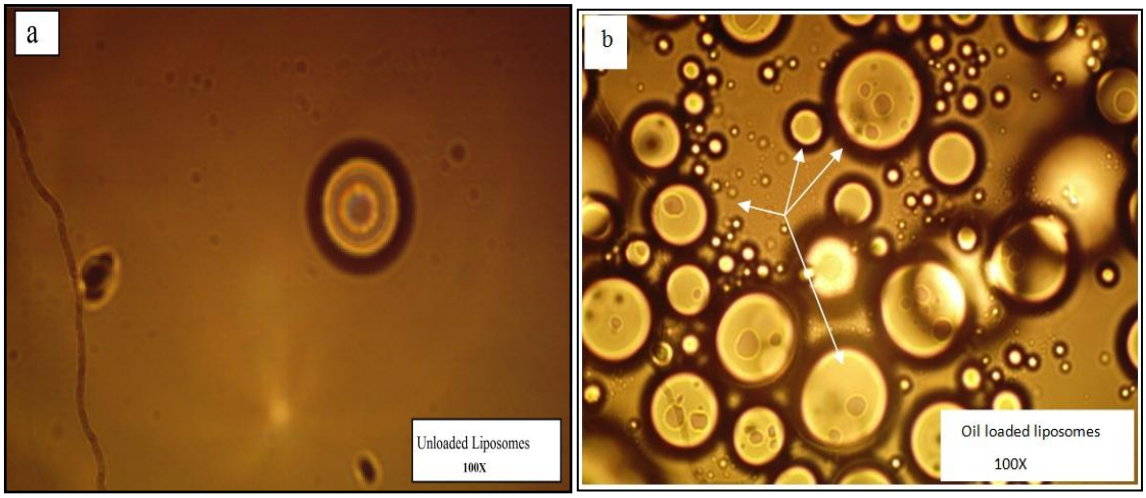

Figure 6.3. Polarized Light Microscopy images of a. UL1 at 100X
b. L1 at 100X

6.4.2. Atomic Force Microscopy

Since light microscopy is unable to provide comprehensive information about the lipid bilayers, AFM was carried out for more detailed information. Because of the deposition of large aggregates, some samples were diluted before being applied onto the slide. AFM images provided a three dimensional view of liposomes and are presented in Figures 6.4a and 6.4b.

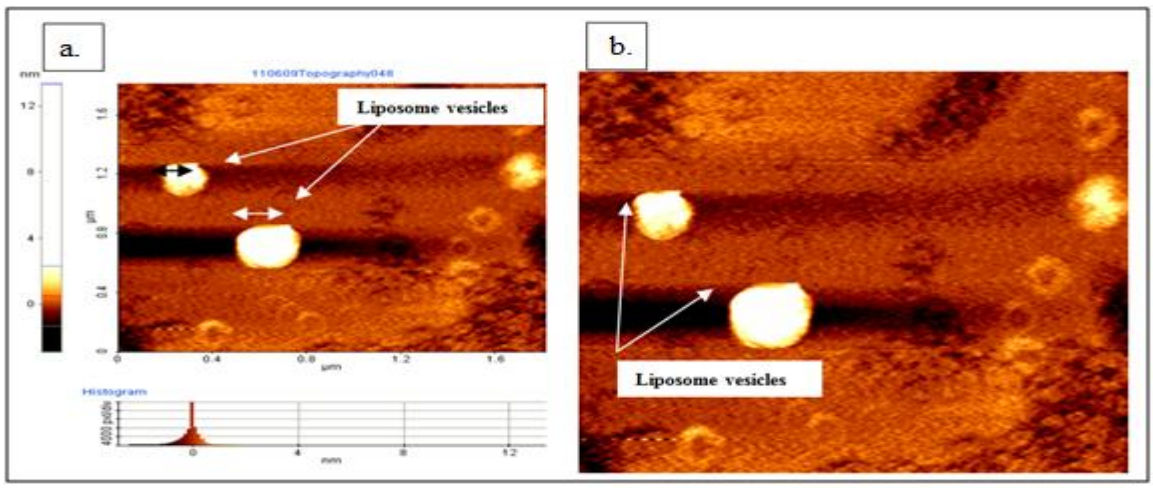

Figure 6.4. 3D Images of Loaded liposomes L1 (Topography of vesicles)

Loaded liposomes showed homogenous, spherical shape and intact bilayer structure vesicles. No difference was observed between AFM images for L1 and L2 vesicles.

According to the results of the liposome characterization studies L1 (7:1:2) molar ratio displayed better properties than L2 (10:1:4) loaded liposomes (Table 6.2) in terms of size, PDI and zeta potential.

6.5. ANTIMICROBIAL ACTIVITY TESTING

6.5.1. Antimicrobial Activity By Agar Well Diffusion Assay

The antimicrobial activity of loaded liposomes (L1 and L2) (50 % v/v) were examined after 120 hrs of incubation chosen according to bacterial growth requirements (*e.g P. gingivalis* 72 h) and the slow releasing nature of liposomes. The antimicrobial activity results of 120 h are presented in Table 6.3 and Figures 6.5.

Table 6.3. Antimicrobial activity of L1 and L2 against oral microorganisms following 120 h incubation

Zone of Inhibitions (ZI's) (mm)		
Test microorganism	**L1**	**L2**
S.mutans	19.0 ± 0.0	16.0 ± 0.0
F.nucleatum	15.3 ± 0.5	21.0 ± 0.0
P.gingivalis	23.3 ± 0.5	20.0 ± 0.0
P.intermedia	16.0 ± 0.0	13.2 ± 0.0
A.a	17.0 ± 0.0	16.6 ± 1.1
C.albicans	30.0 ± 0.0	30.0 ± 0.0
*Mix**	13.0 ± 0.0	12.0 ± 0.0

* Mixed-species of *A. actinomycetemcomitans. P. gingivalis, P. intermedia, F. nucleatum, S. mutans, A.a*
Values are calculated as the mean ±standard deviation of three experiments.
L1: P85G:SA:CHOL(7:1:2)
L2:P85G:SA:CHOL(10:1:4)

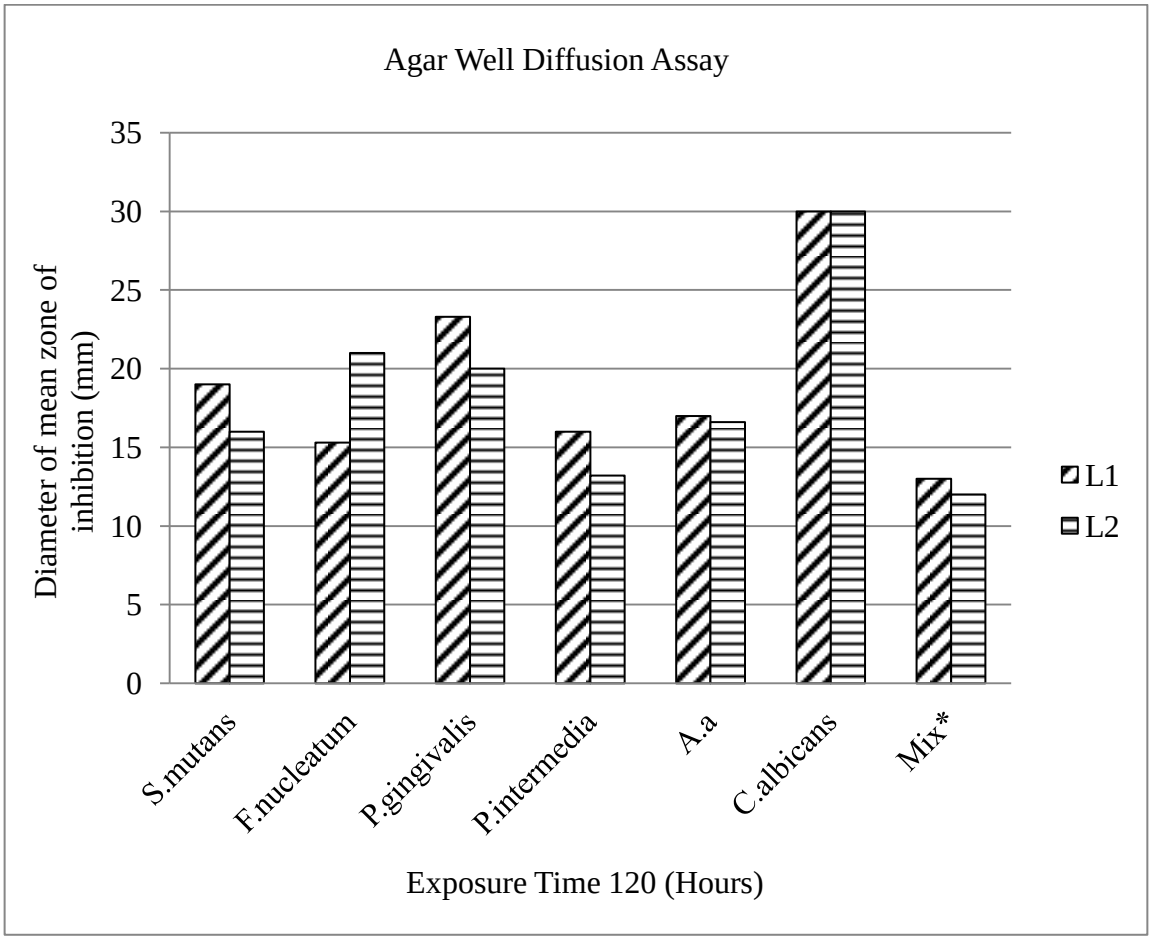

Figure 6.5. Inhibition zones of loaded liposomes L1 and L2 on test microorganisms

Free essential oil was used as a positive control in order to confirm its antimicrobial activity against all microorganisms. Strong, moderate and weak antimicrobial activity of free EO was determined. The highest antimicrobial activity of free EO (control) was observed with the largest ZI against *A.a* (56 mm) after 120 h. Following *A.a*, free EO displayed very strong antimicrobial activities against *C. albicans* (48 mm), *S. mutans* (39 mm) and *P. gingivalis* (36 mm), respectively. A strong antimicrobial activity was observed with *P. intermedia* and *F. nucleatum*, while a moderate one was seen against the mixed culture (18 mm).

After EO encapsulated into liposomes, antimicrobial assay results showed that best antimicrobial activity for both L1 and L2 were observed against *C. albicans* with both liposomes showing a ZI of 30 mm. Conversely, the weakest antimicrobial response was observed against the mixed culture for both L1 and L2 (13.0; 12.0), respectively.

Following the very strong response against *C. albicans,* L1 displayed a strong antimicrobial efficacy against *P. gingivalis* with 23.3 mm, while moderate activities were observed against *S. mutans* (19 mm), *A.a* (17 mm) and *P. intermedia* (16 mm), respectively. A weak response against *F. nucleatum* (15.3 mm) was observed. Statistical comparison of the antimicrobial activity between species displayed no significant antimicrobial effect ($p>0.05$) with L1 between *P.intermedia and F.nucleatum*. On the other hand, a significant difference ($p<0.05$) in comparison between *S.mutans, P.gingivalis, C.albicans* and *A. a.* species was observed.

Following *C.albicans* (30 mm) L2 showed its second strongest antimicrobial effect against *F. nucleatum* (21mm) and moderate responses against *P. gingivalis* (20 mm), *S. mutans* (16 mm) and *A.a* (15.5 mm). A weak response was observed for *P. intermedia* (13.2 mm). Comparison between individual species revealed the antimicrobial activity of L2 loaded liposomes on *F.nucleatum*, *A.a*, *S.mutans* and *P.gingivalis* to show no significant difference ($p>0.05$). The difference between antimicrobial effects of *C.albicans* and mix of microorganisms was significant ($p<0.05$).

Comparison between the efficacies of L1 and L2, revealed no statistical significance for all microorganisms ($p>0.05$).

7. DISCUSSION

7.1.1. CHEMICAL COMPOSITION OF ESSENTIAL OIL (GC-MS)

Plants are a good source for use as drugs for the treatment of many ailments and diseases. They naturally manufacture many different chemical components as a major part of their defense mechanism. Most of these chemical substances are desirable as they are widely used to protect living organisms from unwanted pathogens such as insects and microorganisms [169, 170]. Therefore, phytotherapy provides unexplored natural resources for the development of potential new drugs that can be used in various areas including dentistry and medicine [169, 170]. *S.hortensis L.* from the Lamiaceae family is one of the plants with a high treatment potential, due to its diverse chemical composition which includes; flavonoids, mono-, di-, and sesquiterpenoids, flavones, triterpenoids, and steroids [143, 171].

This study extracted and characterized the EO from dried aerial parts of the plant *S. hortensis L.*, by hydrodistillation method. The chemical composition of the volatile oil was qualitatively and quantitatively analyzed by GC-MS and the most abundant antimicrobial components were notably carvacrol (41.65 %), thymol (10.29 %), and monoterpenic hydrocarbons, p-cymene (16.16 %) [142, 169, 170, 171]. These components make the EOs of *Satureja* species amongst the strongest plant EOs with regards to their antimicrobial properties which have been confirmed and extended in this study [172, 173].

Several factors including; location, climate, geography, genotype, geology, seasonal changes of growth, harvest and experimental conditions are known to affect the chemical composition of plant extracts [174]. These effects have been observed between chemical compositions from different *Satureja* species in different areas of the world [175]. For example, EO extracted from *S. montana* collected from central parts of Dalmatia displayed carvacrol (84 %) as their major components [142]. In Iran, *S. rechingeri* was identified with fifty three components and carvacrol (56.1%), p-cymene (14.0%), and α-thujone (4.7%) were the main components [144]. *S. montana* has shown a high content of phenolic carvacrol (45.7%) and its minor components as p-cymene (12.6%), ɣ-terpinene (8.1%) and

oxygenated constituents carvacrol methyl ether (11.0%), borneol (4.8%), thymol (3.9%) and thymol methyl ether (2.3%). In contrast, *S. cuneifolia* contains the hydrocarbon β-cubebenesesquiterpene (8.7%) and shows a low percentage of carvacrol and thymol compared to *S. montana* [151].

Studies on different *Satureja* species in Turkey have also shown variations in their components. Carvacrol has been observed as the main constituent in *S. icarica*, *S. pilosa,* and *S. boissieri* EO [171]. *S. coerulea* included some sesquiterpenes [177]. 80 compounds were identified in the EO of *S. biflora* and included spathulenol (11.9 %), α-bisabolol oxide-B (8.77%), terpinen-4-ol (7.12%), linalol (6.03%) and bornyl actateta (4.75%) [151]. *S. hortensis* EO extracts have also shown similar qualitative components but quantitative variations amongst different strains [169, 172, 178].

Carvacrol and thymol are isomeric compounds containing (1-methylethyl) an oraphenol group in their structure. The only and main variation between these two phenolic derivatives is in the position of the hydroxyl group on their phenol rings [176]. These changes in position affect their biological activity. This occurs because of the difference in attachment to the cell membrane [179].

Many reports have shown that, carvacrol, thymol, and p-cymene have antimicrobial properties [171] and are well known growth inhibitors against a diverse range of microorganisms and fungi [172]. Minor components such as p-cymene, have also been seen to interact with other components in the EO, thereby affecting its antimicrobial potential [177]. It has been reported that p-cymene alone is an less effective antimicrobial agent. However, its combination with other components has shown synergistic activity, resulting in the destabilization of the microbial membrane [175]. Conversely, reports on the role of p-cymene as an antimicrobial agent have shown an antagonistic effect between phenolic monoterpenes, thymol, carvacrol, and p-cymene in *S. hortensis* EO [174].

This study used the whole essential oil rather than its individual components to utilize the synergistic effects of the diverse major and minor components present in its EO.

7.2. PREPARATION AND CHARACTERIZATION OF LIPOSOMES

7.2.1. Liposomes for the Incorporation of EO of *S. hortensis L.*

Although numerous methods for preparing liposomes have been published [180] only a limited number have been used in application. The first requirement for production is that the method should be simple and reproducible. According to Bangham et al., in 1965, it was found that the thin film hydration method was the simplest and suitable method [156, 157]. This study used the thin film method for successful preparation of liposomes.

The characteristics of liposomes, (Size and Zeta potential, PDI) were strongly influenced by the type of lipids used for preparation [179]. In our study, liposome formulations were prepared with phospholipid 85 G, stearylamine and cholesterol in different ratios as primary substances [156]. According to Bangham et al., the lipids (PL85 G, CH and SA) were dissolved in 5 ml choloroform including 0.1% ethanol [140]. The liposomes were prepared in two different molar ratios; PL85 G: SA: CHOL were used in a ratio of 7:1:2 and 10:1:4 , respectively.

The incorporation of *S. hortensis L*. EO into lipid vesicles as a model drug is based on the function of the lipid composition and may be attributed to their electrostatic and hydrophobic interactions [181]. The combination of liposomes and EO may have hydrophobic interactions and an antimicrobial effect on cell surfaces by non-specific interactions with target microorganisms due to the charge of the membranes.

Since, eukaryotic and bacterial cells possess negatively charged surfaces, this study prepared positively charged liposomal vesicles in order to provide the best liposome surface –bacterial cell interaction. This was accomplished by the use of stearylamine which induces a positive charge to liposome surfaces. However, the EO has strong negative charge due to the lipid structure of the oil. However, the charge liposomes have better attraction to microorganism’s cell surface than neutral liposome. Positively charged liposomes have previously been shown to be suitable for drug delivery to the oral cavity, due to their affinity to the anionic cell membrane [182]. In one study, positively charged liposomes with 1, 2-dipalmitoyl-3-trimethylammonium-propane (DPTAP) was used as a

drug delivery system to the oral cavity. However, it was not found suitable enough for application to the oral cavity, since saliva constituents may interact with liposomes and cause a sudden drop in turbidity of saliva in oral cavity [182, 183].

This study also used cholesterol for liposome production, which is known to cause changes in the degree of head group dissociation and probably in the interaction with lipophilic compounds. Cholesterol molecules orientate with its steroid nucleus among the fatty acyl chains of phospholipid molecules and its hydroxyl group faces on the water side. Thus, cholesterol is often added to liposomes to improve their in vivo and in vitro stability [3, 184].

7.3. CHARACTERIZATION OF LIPOSOMES

Prepared liposomes were evaluated according to their mean particle size, size distribution analysis, zeta potential parameters and PDI values. Also microscopic techniques were performed for characterization in terms of surface morphology of liposomes (vesicles).

7.3.1. Mean particle size, size distribution, zeta potential and PDI

The data statistically showed that L1 loaded liposomes had significantly different mean particle sizes than L2 loaded liposomes ($p < 0.05$) (appendix p. 99). The reason behind homogenization of liposome suspensions is to decrease the size of the liposomes, as well as to keep the size distribution at a minimum, thereby improving the macroscopic appearance of the suspension and also improving the physical stability of the system in terms of sedimentation or floating [184].

Temperature and lipid composition are some of the variables that influence liposome size. Because the liposome suspensions were filtered through a filter medium with a 200 nm and 400 nm pore size, one would expect the size of the resultant liposomes to be smaller than or equal to this value. In our study, the size of unloaded liposomes was observed lower than 200nm (146.9 ± 2.8 and 147.8 ± 2.1 nm) according to DLS.

Liposomes are extruded through polycarbonate filters at temperatures higher than their transition temperatures, meaning as they pass through the 200 and 400 nm pore, they are in a fluid state, are easy to deform and can therefore sometimes, regain their initial size after extrusion. The transition temperatures for PL85G, was room temperature so for the extrusion process 30 $^{\circ}$C was used. Another phenomenon which could explain the increase in liposome size, post extrusion, is secondary particle growth. With certain mixtures of lipids, liposome sizes reach a minimum, followed by a re-increase in size with further extrusion cycles. Fusion, which is a gradual increase in size of bigger particles at the expense of smaller ones by means of molecular diffusion, could be the reason behind secondary particle growth [184].

Moreover, the results showed that the mean particle size of unloaded liposomes were smaller than loaded liposomes. This is expected as it is known that empty vesicles are always smaller than loaded ones. This is a result of higher cohesion and packing among the apolar chains in vesicular membrane [185].

Furthermore, zeta potential values of liposomes were evaluated. The zeta potential is a function of the overall charge of a particle and changes in size can affect aggregation or fusion [186]. Zeta potential measurements of liposomes provide direct information on the structure of the lipid head group. The significance of zeta potential is that its value can be related to the stability of colloidal dispersion. Zeta potential indicates the degree of repulsion between adjacent, similarly charged particles in a disperse system. For particles that are small enough, a high zeta potential will confer stability; dispersion will resist aggregation. When the potential is low, attraction exceeds repulsion and the dispersion will flocculate. Therefore, disperse systems with high zeta potentials (negative or positive) are electrically stabilized while those with low zeta potentials tend to coagulate [184, 186]. The optimum value should be around 25 mV. It can be concluded that the studied formulations were relatively stable.

From the zeta potential measurements in Table 6.2, the zeta potentials for UL1 and UL2 formulations were positive 34.8 ± 2.2 mV and 46.5 ± 1.8 mV, respectively. Following loading with EO, the zeta potential of vesicles were -36.6 ± 0.7 mV for L1 and -29.9 ± 1.7 for L2 loaded liposomes. Furthermore, when all the zeta potential values were statistically

evaluated, it was determined that UL1 and UL2 have significantly different zeta potential values ($p<0.05$) and following loading with EO liposomes, the zeta potential values of L1 and L2 were significantly different ($p<0.05$). After incorporation loaded liposomes became negatively charged, due to the lipid structure of the oil.

It has been reported that low PDI values (≤0.3), indicate a homogenous vesicle population. Larger PDI values (>0.3), indicate a high heterogeneity [167]. When the PDI values were statistically evaluated for all liposomal formulations, results showed that PDI values of the UL1 and UL2 unloaded liposomes were not significantly different ($p>0.05$). However, L1 and L2 loaded liposomes showed significantly different PDI values ($p< 0.05$). This is due to the heterogeneous particle size distribution PDI value of L1 (0.41 ± 0.02) which is larger than 0.3 and the homogenous particle size distribution PDI value (0.16 ± 0.07) of L2 (smaller than 0.3). Although, the L2 formulation was seen to be more homogenous than the L1 formulation, this was observed due to the aggregation of the vesicles, leading to low PDI values for L2.

7.3.2. Morphological characterization of liposomes (PLM and AFM)

Liposomes were further examined by PLM and AFM in order to evaluate their morphological structures i.e. bilayer structures. According to the images formulations L1 and L2 were MLV type vesicles.

The microscopic examination of liposomes confirmed that L2 had a larger size thatn L1 supporting particle size data (L2= 2171 ± 151.0, L1= 412.5 ± 13.93). These findings confirm aggregation has occurred in L2, and leads us to conclude that L1 formulation has better characterization properties than the L2 formulation. Furthermore, microscopic examination revealed L1 vesicles to have an intact shape and a homogenous distribution (Figure 6.3 and 6.4). Therefore, according to overall results of the characterization studies L1 was observed as the more suitable liposome to be used in this study.

7.4. ANTIMICROBIAL ACTIVITY TESTING

Studies on the antimicrobial mechanism of EOs have shown that they generally affect bacterial cell membrane functions such as; electron transport, nutrient uptake, protein and nucleic acid synthesis and enzyme activity. This results in a change to the membrane permeability, thus causing release of intracellular components and eventually cell death [116, 151]. Several studies have shown the antimicrobial activity of plant EOs against different cariogenic and periodontopathic bacteria [187-189]. The EO of *Shitake* mushroom, demonstrated significant antimicrobial activity on several periodontal pathogens [190]. Moreover, EOs from traditional Asian herbs, namely *Wakame, Houjicha, Genmaicha* and *Sencha* teas were tested on four oral pathogens involved in periodontitis. Results displayed all EOs to have antibacterial properties [191].

A comparative antimicrobial study on the EO from different *Satureja* species, showed *S. hortensis L.* EO to have the strongest antimicrobial effect against bacteria, yeast and fungi [144]. This effect has been attributed to the high contents of monoterpenes and oxygenated compounds, such as γ-terpinene, p-cymene, thymol and carvacrol [169, 172, 173]. Similar to our findings, Gursoy and Cakmakcı found that free EO which was extracted by hydrodistillation method for 3h from *S.hortensis* from the southern west part of Turkey also had antimicrobial activity against *A. actinomycetemcomitans*, *P. gingivalis*, and *F. nucleatum*. Diktas and Sahin also reported that the EO of *S. hortensis* had a very strong fungicidal effect on *A. flavus* [154]. Furthermore, *S. hortensis* L. EO has previously shown inhibitory effects on two phytopathogenic fungi *Alternaria mali* and *Botrytis cinerea* [149].

Investigations on *S.hortensis* L. EO have also reported conflicting results. *S.hortensis* L. EO from Serbia, displayed an antimicrobial activity against *B. subtilis*, whereas a strain from Yusufeli in Turkey did not exhibit any antimicrobial effect against same bacteria [136]. As with our present findings, it has been found that the EO of *S.hortensis* successfully inhibited phytopathogenic fungi and some food spoilage fungi including *C. albicans* [187]. However, in contradiction, another study found no antimicrobial affect against *C. albicans* [192]. These conflicting results could be due to many factors including; strain type of plant, bacterial strain studied, geographical location of plant, extraction process, experimental parameters, part of plant used and other environmental factors.

The use of liposomes as a drug delivery system is fast becoming the method of choice based on the advantageous properties that differ according to its formulation. Some studies have shown that encapsulation of certain substances are able to increase bioavailability and thus enhance its bioactive properties [169, 170]. While others, have shown a decrease in cytotoxicity due to the slow releasing nature [161, 165].

To date there are no reports on the antimicrobial activity of liposomal incorporation of EO from *S.hortensis L*, or on liposomes against oral microorganisms. However, several studies relating to liposomal incorporation of other plant extracts and their antimicrobial effects have been carried out [77, 169, 170]. Following the liposomal incorporation of *Artemisia arborescens* EO an increase in antiviral activity against *Herpes simplex* viruses was observed [77]. Antiviral assay results also showed that *A. arborescens* incorporated EO increased its *in vitro* antiherpetic effect.

The major components of *Origanum dictamnus* EO have previously been successfully encapsulated into phosphotidyl choline-based liposomes. Results showed antimicrobial properties against *S.aureus, S.epidermis, P.aeruginosa, E.cloacae, K. pneumoniae, E.coli, S.mutans, S.viridans, C.albicans, C.tropicalis, C.glabrata* and *L.monocytognes* [169]. Although this study did not compare the antimicrobial effect of free EO with loaded liposomes due to the difference in concentrations, a slow releasing property of the EO over a period of 120 h was observed (appendix p. 107). Kinetic studies and time kill assays will need to be performed in order to confirm this.

The antimicrobial efficiency of antimicrobial compounds may differ, according to the Gram type of the test microorganism [193]. Gram-positive organisms are said to be more sensitive than Gram negative ones. This is due to the presence of an outer membrane, surrounding the cell wall of Gram negative bacteria, making it less susceptible to the antibacterial substances. This outer membrane may restrict the diffusion of hydrophobic compounds through its lipopolysaccaride covering. On the other hand, Gram positive bacteria are always in direct contact with the hydrophobic constituents thus enabling binding to the phospholipids bilayer of the bacterial cell membrane, thereby increasing ion permeability [194].

Liposomal formulations have been studied for their use in overcoming reduction in cellular resistance by overcoming cellular permeability [195, 196]

Results from the present study have shown no discrimination in antimicrobial activity based on Gram type. L1 and L2 liposomes exhibited varying degrees of antimicrobial activity against all tested microorganisms. These results cannot be correlated with the Gram stain of the bacteria, i.e. cell membrane, or with its respiratory functions (aerobic or anaerobic). Findings may suggest a possible therapeutic role for these liposomes against both bacterial groups.

The weak inhibition activity observed for both L1 and L2 on the mixed culture is to be expected since, bacteria grow in communities known as biofilms and therefore cell to cell communication (quorum sensing) and possible surface alterations allow the bacterium to reduce its interactions with the antimicrobial compound, thus making it resistant [197]. Further studies are required in order to understand the resistance mechanism of these microorganisms against antimicrobial compounds, which may contribute to the present results.

8. CONCLUSION

S. hortensis EO can successfully be incorporated into liposome formulations L1 (P85G (7:1:2) and L2 (P85G (10:1:4) loaded liposomes by the Bangham method. Furthermore, following 120h incubation antimicrobial activity was observed against all test microorganisms.

To the best of our knowledge, this is the first study showing the successful incorporation of *S.hortensis* EO into two different liposome formulations suitable for antimicrobial use in the oral cavity. Such data suggest that incorporation of EO in liposomes could be useful in the management of oral infections induced by oral microorganisms.

Therefore, further detailed studies are necessary in order to understand the mechanisms, kinetics and time release properties of liposomes. and develop effective formulations.
