Title of the Master's Thesis : 3D Object Recognition By Using 3D Point Clouds

Name/Last Name of the Student : Yusuf Gökhan Yavuz

Date of Thesis Defense : 03/09/2013

The thesis has been approved by the Graduate School of Natural and Applied Sciences.

Asst. Prof. F. Tunç BOZBURA

Acting Director

This is to certify that we have read this thesis and that we find it fully adequate in scope, quality and content, as a thesis for the degree of Master of Science.

Examining Committee Members:

Asst. Prof. Dr. Övgü ÖZTÜRK :

Asst. Prof. Dr. Devrim ÜNAY :

Asst. Prof. Dr. Egemen ÖZDEN

ACKNOWLEDGMENTS

I would never have been able to finish my master thesis without the guidance of supervisor Asst. Prof. Dr. Övgü ÖZTÜRK, help from friends, and support from my family and wife also my colleague.

I would like to express my deepest gratitude to my advisor, Asst. Prof. Dr. Övgü ÖZTÜRK, for her excellent guidance, caring, patience, and providing me with an excellent atmosphere for doing research. I would also like to thank my thesis partners Bahtiyar Kaba, Hüseyin İnan and Mustafa Tosun.

I would like to thank Metin Göğüş and Emre Begen, who as a good friend, was always willing to help and give his best suggestions. Many thanks to my colleague Akın Söylemez, Alper Gündüz Hayati Demirbaş, Harun Markopcuoğlu, and other friends for suggesting me. My research would not have been possible without their helps.

I would also like to thank my parents and parents in law, two sisters, and my cat. They were always supporting me and encouraging me with their best wishes. I also want to thank my relatives to show patience to me for not visiting them. Finally, I would like to thank my wife, Aliye YAVUZ. She was always there cheering me up and stood by me through the good times and bad.

ÖZET

3 BOYUTLU NOKTA BULUTU KULLANARAK 3 BOYUTLU NESNE TANIMA

Yusuf Gökhan Yavuz

Bilgisayar Mühendisliği

Danışman: Yrd. Doç. Dr. Övgü ÖZTÜRK

Eylül 2013, 55 Sayfa

Akıllı sistemlerin en önemli parçalarından biride nesne tanıma sistemleridir. Nesne tanıma bir çok gelişmeye değişik alan ve endüstrilerde öncülük etmiştir. Örneğin askeri, sağlık, ulusal güvenlik, bankacılık, kültürel miraslar, ... vb. Bu çalışmada ICP kullanarak kültürel bir 3 boyutlu nesne üzerinde yine bu 3 boyutlu nesne ait bir nesneyi tanımaya çalıştık. ICP methodu 3 boyulu bir nesne ile kesilmiş olan 3 boyutlu nokta bulutu ile minimum uzaklıkları karşılaştırarak çalışır. Daha sonrasında tekrarlı olarak dönme ve öteleme matrislerini bularak aralarındaki uzaklığı iki nesne en yakın eşleşmesine kadar devam eder. 3 boyutlu nesne tanımada ICP kullanmanın en büyük avantajı hızlı olması ve parçalı eşleştirme yapabiliyor olmasıdır. ICP'yi 4 farklı nokta bulutu ve 3 boyutlu nesne üzerinde değerlendirmeye tabi tutulup etkinliği gösterilmiştir.

Anahtar Kelmeler: Nesne Tanıma, 3 Boyutlu Eşleştirme, Nokta Bulutu, ICP

ABSTRACT

3D OBJECT RECOGNITION BY USING 3D POINT CLOUDS

Yusuf Gökhan Yavuz

Computer Engineering

Supervisor: Asst. Prof. Dr. Övgü ÖZTÜRK

September 2013, 55 Pages

Object recognition systems are one of the most important part of the intelligent systems. Object recognition has led many developments on different areas and industrials such as medical, military, national security, banking, cultural heritages, ... etc.. In this study, we work on a cultural object to recognize a 3D object in a 3D point clouds by using ICP. This method based on comparing minimal distances between points on the 3D object and points on the sliced parts of 3D point clouds. Afterwards we iteratively calculate rotation and translation matrix for minimizing the distances between two compared object until we find the two closest matching. One of the most important advantage of using ICP for 3D object recognition is getting fast results and partial matching. We evaluate ICP on four different point clouds and 3D objects, and show that it effectively work on different type of point clouds and 3D objects.

Keywords: Object Recognition, 3D Matching, Point Cloud, ICP

1 INTRODUCTION

The rapid evolution in technology (hardware and software) gives huge opportunities to not only researchers or company also regular users to acquire, create and manipulate 3D models. The 3D modelling tools such as MAYA, 3ds Max, AutoCAD and sculpting systems, make it easier to users to create 3D models directly on the computers. On the other hand the 3D digitizing tools for digitizing 3D objects from the real world, and include 3D scanner machines (Leica, LiDAR, Microsoft Kinect ...), registration from range data, automatic modelling from multi-view video, etc. Thus increasing of 3D models both on the internet and standalone leads robust and efficient technique for searching, finding or recognizing 3D models or 3D objects in a data set.

3D model search could be design by using a textual based which can be done by giving user's desired name to models which identifies the semantic meaning of the desired model or class of models. However this method is not useful for model searching. For example an user might give objects' name as "Ferrari" but another user might use "Luxury Car" for the same model. So if a common user who wants to find "Car" could not find either "Ferrari" or "Luxury Car". It is also impossible to use same annotating for every user.

Currently, popular approaches in object recognition focus on two trends: one is the appearance-based methods (Murase and Nayar, 1995; Fergus et al., 2006) and the model-based methods (Gardner and Lawton,1996; Romdhani et al., 2002).

Figure 1.1 Different photos of same car and different angle of light source (Tingbo Hou,Sen Wang et al.,2011)

In appearance-based methods, objects are typically represented by a group of feature vectors. A set of positive and negative examples of classifier spanning on the principle component analysis subspace or feature subspace is accepted to train. In practice, technical issues occur from appearance variation due to different pose and lightings. Model-based methods require a set of 3D models to provide geometric constraints. When object place is determined, usage of 3D models is to solve the problem of next matching. However, it stands on two basic assumptions: first, the 3D model can precisely fit to the input images. Second, pose estimation is accurate enough. To estimate appearance of objects, global and local clues have been used to simulate texture of the 3D model. Despite the progress, it still has limited success in illumination variations, since illumination conditions can dramatically affect appearances as shown in Figure 1.1

Also in 3D model object recognition, there are many challenges which are listed in the following.

- (1) Automation: When request a 3D model, the 3D model should be automatically find in 3D data.
- (2) Efficiency: 3D object recognition should be efficient. 3D model object recognition should be fast especially in small data.
- (3) Scope: 3D object recognition should work well in various kinds of 3D models.
- (4) Strongness: 3D object recognition should be developed against geometric processing, such as similarity transformation (translation, rotation and scaling), connectivity changes (remeshing,sub-division and simplification), model degeneracy (missing, wrongly oriented, intersecting, disjoint and overlapping polygons), random noise, smoothing, deformation, and posture changing, etc.
- (5) Discrimination: 3D object recognition should be sensitive to preserve important distinctions through 3D models.

2 3D OBJECT RECOGNITION

Object recognition systems are deeply rooted component that are built into modern intelligent systems. Research on object recognition algorithms has led to advances in factory and office automation through the creation of optical character recognition systems, assembly-line industrial inspection systems, as well as chip defect identification systems. It has also led to significant advances in medical imaging, defence and biometrics.

First appearance of recognition systems also appeared in biomedical research for the chromosome recognition task (G. Gallus, et al. 1968, 1974). Even though people did not understand importance of the, its importance became clearer later. Recognition technologies are also successfully used in the food industry (e.g., for the automated classification of agricultural products (A. Jimenez, et al., 2000), the electronics and machinery industry (for automated assembly and industrial inspection purposes (E.N. Malamas, E.G.M. Petrakis, M. Zervakis, et al. 2003), and the pharmaceutical industry (for the classification of tablets and capsules) (M. Ejiri, 2007). Many of the models used for representing objects are also effectively employed by the medical imaging authority for the robust segmentation of anatomical structures such as the brain and the heart ventricles (T. McInerney, D. Terzopoulos, 1996) (A. Andreopoulos, J.K. Tsotsos, 2008). Handwritten character recognition systems are also employed in mail sorting machines as well as for the digitization and automated indexing of documents (O.D. Trier, A.K. Jain, T. Taxt, 1996) (S. Mori, H. Nishida, H. Yamada, 1999). Furthermore, traffic monitoring and license plate recognition systems are also successfully used (K. Takahashi, T. Kitamura, et al, 1996) (C.-N. Anagnostopoulos, I. Anagnostopoulos, et al. 2008) as are monetary bill recognition systems for use with ATMs (M. Ejiri, 2007). Biometric vision-based systems for fingerprint recognition (D. Maltoni, D. Maio, A.K. Jain, S. Prabhakar, 2009), iris pattern recognition (K.W. Bowyer, K. Hollingsworth, P.J. Flynn, 2008), as well as finger-vein and palm-vein patterns (C.-L. Lin, K.-C. Fan, 2004) (N. Miura, A. Nagasaka, 2005) have also gained acceptance by the law enforcement community and are widely used.

Despite the success of recognition systems that are featured for specific task, improved solutions to the more general problem of recognizing complex object classes. They are uncatchable under poorly controlled environments. Furthermore, there is no universal agreement on the definitions of various vision subtasks. Often experienced terms in the literature such as detection, localization, recognition, understanding, classification, categorization, verification and identification, are often ill defined, leading to confusion and ambiguities.

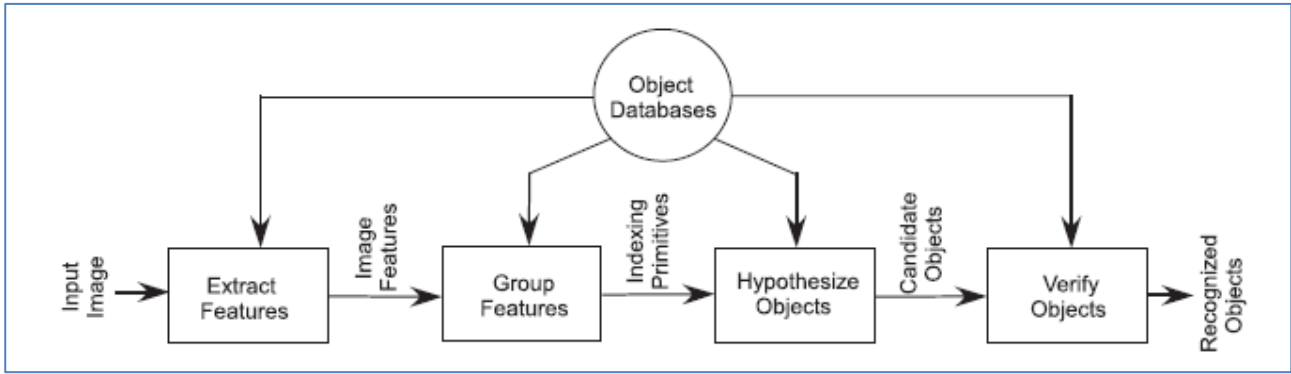

Figure 1.2 The components used in a typical object recognition system (J. Tsotsos ,1992) (S. Dickinson, 1999)

Purpose of this section is to give information about 3 main types of 3D object recognition method. These are RGB, RGB-D and Depth Data. However this is our categorization method on general categorization are recognition using volumetric parts, Automatic programming, Perceptual organization, Interpretation tree search, Geometric invariants, Qualitative 3-D shape-based recognition and deformable models, Function and context, Appearance based recognition, Local feature-based recognition and constellation methods, Grammars and related graph representations (Alexander Andreopoulos, John K. Tsotsos, 2013)

2.1 RGB

The earliest applications based on RGB were pattern recognition systems for character recognition in office automation related tasks (L.G. Roberts,1960) and (J.T. Tippett, D.A. Borkowitz, et al. 1965). Early work by Roberts in the 1960s (L.G. Roberts, 1963) first identified the need to match two-dimensional features extracted from images with the three-dimensional representations of objects. Other applications were built for chromosome recognition and the analysis of aerial images.

Given more details about chromosome recognition which is closely related to medical area let's explain what is chromosome and why it is important. A chromosome is an organized structure of DNA, protein, and RNA found in cells which contains all information about body. To make a visual examination of a chromosome image for various chromosome abnormalities, individual chromosome regions have to be determined in the subject image and classified into the distinct chromosome types image chromosome images for various chromosome abnormalities plays an important role in many clinical practices including treatment and prevention of genetic disorders,

radiation dosimetry, toxicology, etc. Usually, the visual chromosome examination requires the following procedures (J.Graham and J.Piper 1994) .

1st Staining a set of chromosomes in a cell nucleus and capturing its image,

2nd Determining individual chromosome regions in the subject image,

3rd Classifying the determined regions into the 24 distinct chromosome types (1, 2, . . . , 22, X, and Y).

With proper staining methods (e.g. G-banding method etc.), a characteristic series of light and dark bands appears along the longitudinal axis of a chromosome. The band appearance on a chromosome is called a band pattern, and it is unique to each type of chromosome. For determining and classifying the chromosome regions in an image, individual chromosome regions are extracted from the subject image, the longitudinal profile of intensity on each region is acquired as its band pattern, and the region is classified according to the band pattern. (J.Graham and J.Piper, 1994) (A. Carothers and J. Piper, 1994) (Q.Wu, Z. Liu et al. Castleman, 2005) (M. Moradi and S.K. Setarehdan, 2006)

With proper staining methods (e.g. G-banding method etc.), a characteristic series of light and dark bands appears along the chromosome. The band appearance on a chromosome is called a band pattern, and it is unique to each type of chromosome. For determining and classifying the chromosome regions in an image, individual chromosome regions are subtracted from the subject image, profile of intensity on each region is achieved as its band pattern, and the region is classified according to the band pattern. (J.Graham and J.Piper, 1994) (A. Carothers and J. Piper, 1994) (Q.Wu, Z. Liu et al. Castleman, 2005) (M. Moradi and S.K. Setarehdan, 2006)

Later applications led to progress in pattern recognition, feature detection and segmentation but dealt with objects of a different type. These later approaches are closely related to modern 2D appearance based object recognition research.

Color provides powerful information for object recognition. A simple and effective recognition scheme is to represent and match images on the basis of color histograms as proposed by Swain and Ballard (M.J. Swain, D.H. Ballard, 1991). The work makes a very helpful in introducing color for object recognition. However, it has the drawback that when the illumination circumstances are not equal, the object recognition accuracy degrades significantly. This method is extended by Funt and Finlayson (B.V. Funt, G.D. Finlayson, 1995), based on the retinex theory of Land (E.H. Land, J.J.

McCann, 1971), to make the method Pattern recognition illumination independent by indexing on illumination fixed surface descriptors (color ratios) computed from neighboring points. However, it is assumed that neighboring points have the same surface normal. Therefore, the derived illumination fixed surface descriptors are negatively affected by rapid changes in surface orientation of the object (i.e. the geometry of the object). Healey and Slater (G. Healey, D. Slater, 1995) and Finlayson et al. (G.D. Finlayson, S.S. Chatterjee, B.V. Funt, 1996) use illumination fixed moments of color distributions for object recognition.

These methods are sensitive to stopped object and complicated as the moments are defined as an inseparable attribute on the object as one. In global methods, in general, occluded parts will disturb recognition. Slater and Healey (D. Slater, G. Healey, 1996) to get over this problem by computing the color features from small object regions instead of the entire object.

The choice which color models to use does not only depend on their strongness against varying illumination across the scene (e.g. multiple light sources with different spectral power distributions), but also on their strongness against changes in surface orientation of the object (i.e. the geometry of the object), and on their strongness against object obturation and cluttering. Furthermore, the color models should be brief, differential and strong to noise.

2.2 RGB-D

RGB-D cameras such as Prime Sense, Microsoft Kinect, ... etc. are an emerging trend of technologies that provide high quality synchronized depth and color data. Using active sensing techniques, robust depth estimation is able to be done real time. Microsoft Kinect, originally designed for video games afterwards it turns into a depth camera that has made it into consumer applications. It is a huge success with comprehensive implications for real-world visual perception. One key area of depth camera usage is in object recognition, a fundamental problem in computer vision and robotics.

Figure 2.1 (left) RGB image and (right) depth information captured by an RGB-D camera. Recent systems can capture images at a resolution of up to 640x480 pixels at 30 frames per second. White pixels in the right image have no depth value, mostly due to occlusion, max distance, relative surface angle, or surface material. (Manuel Blum, Jost Tobias Springenberg, Jan Wulping and Martin Riedmiller, 2012)

During the last decades a dozen of different feature extraction methods have been designed for object recognition tasks in computer vision community. These methods mostly use a fixed grid or extract from local image patches around detected interest points. The most important approaches of these are based on orientation histograms such as SIFT (David G. Lowe, 2004) and SURF (Herbert Bay, Tinne Tuytelaars, and Luc Van Gool, 2006). These methods are really hard to design or implement to other environment however these methods was used too many application. A histogram based on generalizing feature called kernel description Figure 2.1 which give a general design pattern for local feature responses and give us additional information in a different way.

To learn low level feature from a data has solved by several different ways. The work on deep belief networks (Geoffrey E Hinton, 2007) and deep autoencoders (Dan C. Ciresan, Ueli Meier, Jonathan Masci, et al, 2011), (Quoc V Le, Jiquan Ngiam, Zhenghao Chen, et al. 2010) resulted in object recognition architectures that can achieve on several benchmarks. Sparseness of the learned feature can be representate such as sparse coding (Adam Coates, Andrew Y. Ng, and Serra Mall, 2011), and local coordinate coding (Kai Yu and T. Zhang, 2010), they have been successfully implement to object recognition duties. Also another interesting method which is unsupervised

feature was developed by Coates et al. on learning (Adam Coates, Honglak Lee, and Andrew Y. 2011).

Flynn and Jain (P. Flynn and A. Jain, 1992) describe an approach for 3D to 3D object matching using invariant features indexing. Solid models of objects composed of cylinders, spheres, planes are used to determine corresponding triples $\{(M_1, S_1), (M_2, S_2), (M_3, S_3)\}$ where M_i represents a model surface and S_i represents a surface of corresponding scene. For each pair of extracted scene cylinders, spheres and planes, an invariant feature is defined and extracted. For example, for each pair of cylinders and planes the angle between the plane's normal and the cylinder's axis of symmetry is removed. Pairs or triples of such invariant features are used to access tables where each table entry contains a linked-list of all the database object models composed of the same invariant features. The table contains votes for each object. As a result the most voted object is recognized by system.

Hoiem et al. (D. Hoiem, A. A. Efros, and M. Hebert, 2006) use probabilistic estimates of 3D geometry of objects relative to other objects in the scene to make estimates of the similarity of the various object hypotheses. Given an example to the system, if a current hypothesis detects a person and a building in the scene or in the image, However the hypothesis assumes that a person taller than the building. Their approach can be united as a "wrapper" method around any object detector. Markov random fields (MRFs) are also a popular method for incorporating contextual information via spatial dependencies in the images (S. Z. Li. Markov, 2001). In more recent work, Kumar and Hebert (S. Kumar and M. Hebert, 2003) use Discriminative Random Fields (DRFs), an extension of MRFs, for merging similar scene interactions. The most important advantage of DRFs is their ability to flexible the conditional independence hypothesis of MRFs. A few researchers use the statistics of bags of localized features (edges, lines, local orientation, color, etc.) to determine the likely distribution of those features depending on the scene or current context (Torralba et al., 2003), (Wolf and Bileschi, 2006), (Siagian and Itti, 2005).

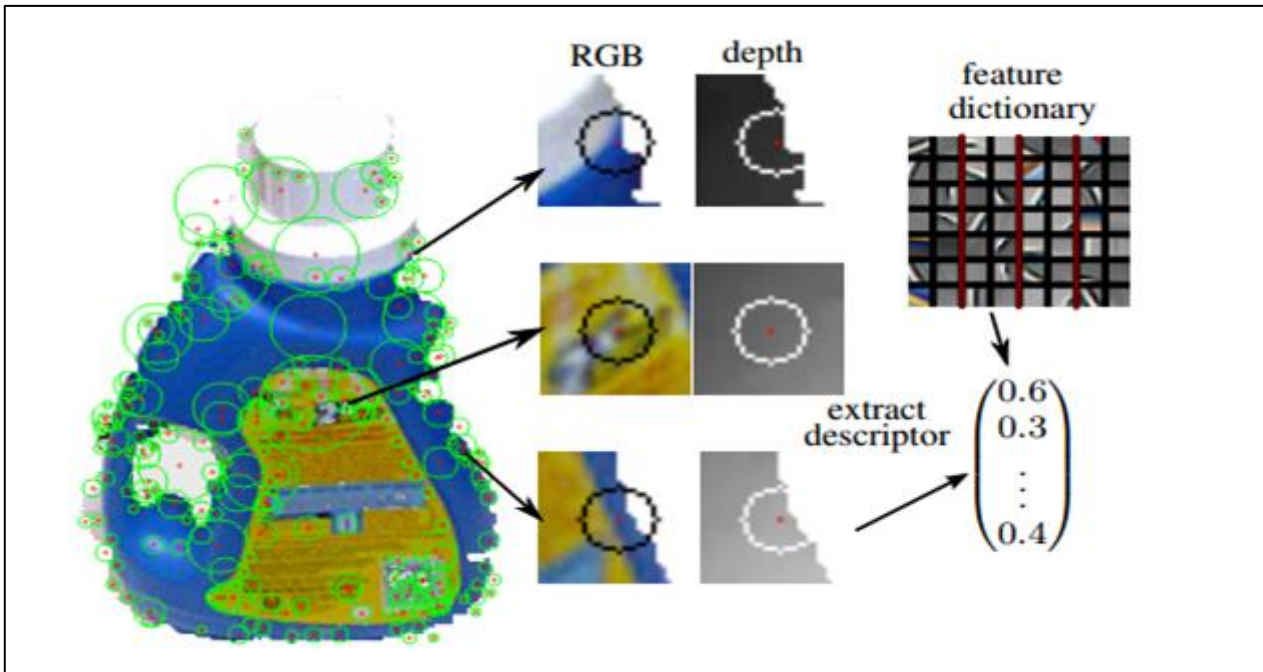

Figure 2.2 The general descriptor extraction procedure for the convolutional k-means descriptor. First, a set of interest points is detected in the input image. Around each interest point a 16x16 px area is extracted. To build the feature descriptor for an image point feature responses from image patches 6x6 px within this area are compared using the learned feature dictionary. (Manuel Blum, et al. 2012)

A Learned Feature (Manuel Blum, et al. 2012)'s method consider a specific recognition setting in which the objects are represented using high resolution RGB-D data and propose to extract a feature histogram descriptor combining information from all 4 channels. To make their approach scalable to high resolution images they adapt the standard setting used by Hessian based approaches and chose to extract their learned feature responses around interest points, effectively substituting the hand designed Hessian descriptors. The descriptor is built from features, which are learned via a k-means approach that is adapted from the previously mentioned work in (Adam Coates, Honglak Lee, and Andrew Y. , 2011) Figure 2.2 their work is similar to work on kernel descriptors (Liefeng Bo, Xiaofeng Ren, and Dieter Fox, 2011) in which a descriptor is built by comparing pixel orientations or color intensities. However, in contrast to this approach they did not explicitly design the used feature responses using pixel comparisons, but decided to learn a representative set of features which is then compared to the vicinity of the detected interest point.

2.3 Depth Data

Retrieval of data based on shape has been studied in several fields, including computer vision, computational geometry, mechanical CAD, and molecular biology.

3D shape retrieval methods can be roughly subdivided into three categories: (1) methods that first attempt to derive a high-level description (e.g., a skeleton) and then match those, (2) methods that compute a feature vector based on local or global statistics, and (3) miscellaneous methods.

Give an example of the first method might be the medial scaffolds (Ming-Ching Chang, Benjamin B. Kimia, 2011) This method typically a major branch in shape representation is the symmetry-based medial axis (MA) representation (K. Siddiqi, S. Pizer (Eds.), 2009) and (H. Blum, 1973). The MA is promising for shape recognition (T. Sebastian, P. Klein, B. Kimia, 2004) and (K. Siddiqi, J. Zhang, et al. 2008) in that (i) it organizes the shape information in a hierarchical, intrinsic graph-like structure (F. Leymarie, B. Kimia, 2007), which enables matching parts of deformed shapes naturally, and (ii) such information captured with the MA is complete in that a full shape reconstruction is always possible (P. Giblin, B. Kimia, 2003). Despite these advantages, the MA is generally sensitive to perturbation and difficult to model in the 3D case (D. Attali, J.-D. Boissonat, H. Edelsbrunner, 2004). Such issues have been recently addressed (F. Leymarie, B. Kimia, 2007). Medial Scaffold (MS) a hierarchical organization of the 3D MA into a hypergraph form (M.-C. Chang, B. Kimia, 2008) and a regularization framework of the MS to deal with the above barriers. The MA instabilities which induce sudden topological changes are formally classified as a set of transitions and thus can be regularized via a set of transforms (M.-C. Chang, B. Kimia, 2008) They proposed to match the regularized MS such as the ones shown in Figure 2.3 to estimate a global similarity between shapes.

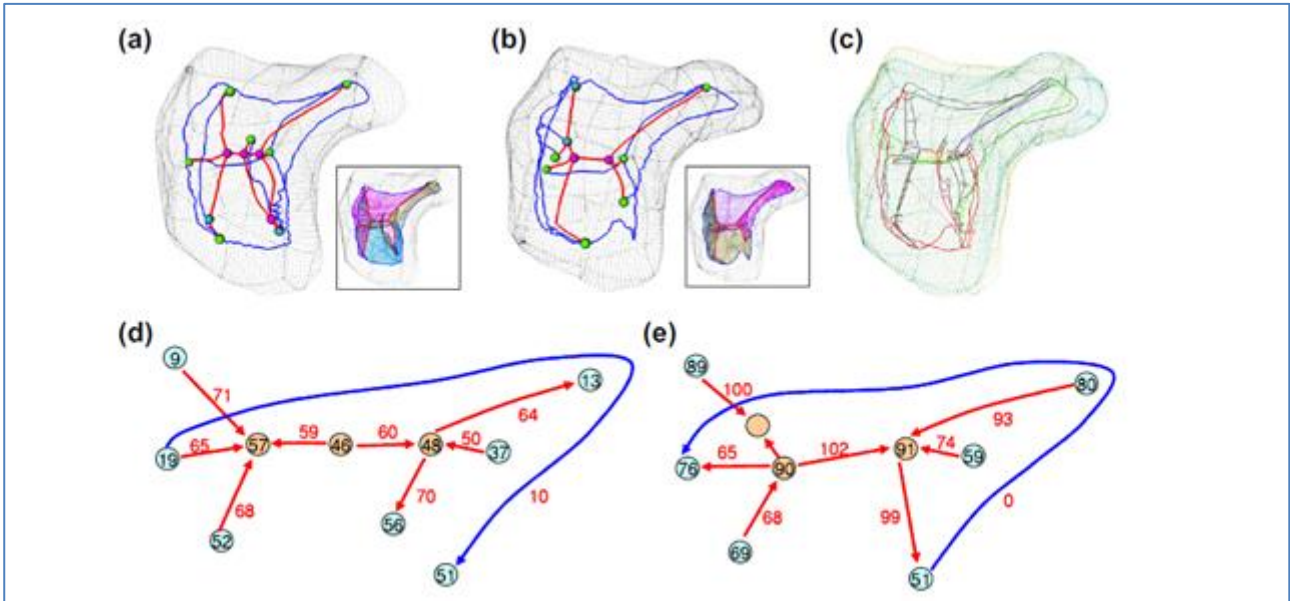

Figure 2.3 shows that the matching of the MS hypergraphs of two carpal bones in (a) and (b) is shown in (c). (d and e) show a manual correspondence, where the graph components are labeled with identification numbers. (Ming-Ching Chang, Benjamin B. Kimia, 2011)

Give an example of the second method might be Shape Distributions method. Main idea is to represent the marker of an object as a shape distribution sampled from a shape function that is measuring global geometric properties of an object. First duty for this approach is to decrease the shape matching problem to the comparison of probability distributions, which is simpler than traditional shape matching methods that require pose registration, feature correspondence, or model fitting. the diversity between sampled distributions of simple shape functions (e.g., the distance between two random points on a surface) provide a robust method for disjunctive between classes of objects Figure 2.4 and Figure 2.5 (e.g., cars versus airplanes) in a moderately sized database, despite the presence of optional translations, rotations, scales, mirrors, tessellations, simplifications, and model corruption. They can be estimated quickly, and thus the proposed method could be applied as a pre-classifier in an object recognition system or in an interactive content-based withdrawal application.

The shape functions are;

- A3: Measures the angle between three random points on the surface of a 3D model.
- D1: Measures the distance between a fixed point and one random point on the surface. We use the centroid of the boundary of the model as the fixed point.

- D2: Measures the distance between two random points on the surface.
- D3: Measures the square root of the area of the triangle between three random points on the surface.
- D4: Measures the cube root of the volume of the tetrahedron between four random points on the surface.

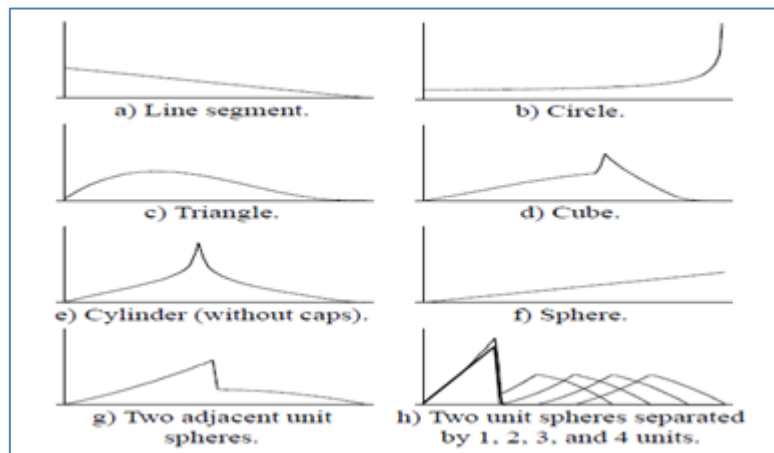

Figure 2.4 Example D2 shape distributions, in each plot, the horizontal axis represents distance, and the vertical axis represents the probability of that distance between two points on the surface.

(Robert Osada, Thomas Funkhouser, et al., 2002)

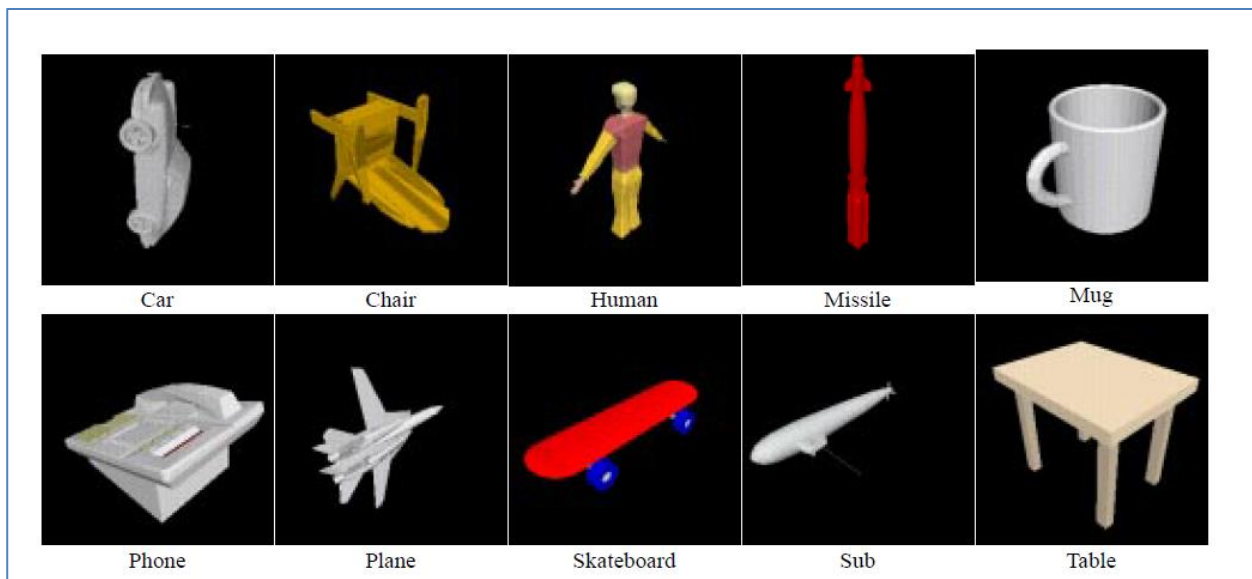

Figure 2.5 chosen object to test based on D2 shape distribution. (Robert Osada, Thomas Funkhouser, et al , 2002)

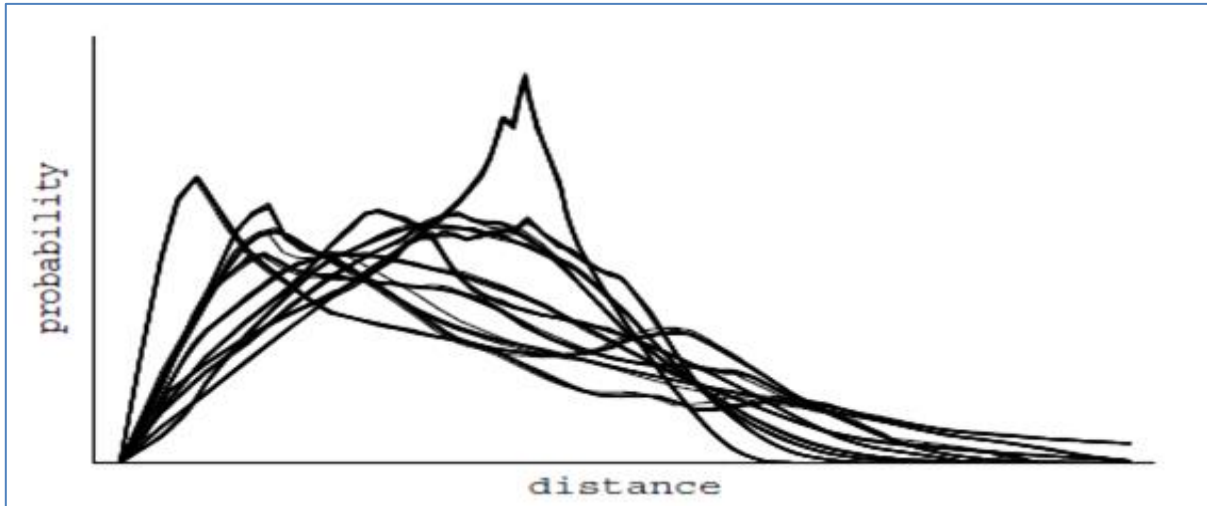

Figure 2.6 D2 shape distributions for seven variants of ten models in Figure 2.5 (Robert Osada, Thomas Funkhouser, et al., 2002)

To give a few examples of the last method might be Prioritized Feature Matching (Y. Li, N. Snavely), Discriminative Sketch-based (T. Shao, W. Xu, et al. 2011) ,Topology Matching method (M. Hilaga, Y. Shinagawa, et al.) , 3D Object Recognition in Range Images Using Visibility Context (E. Kim, 2011) Signature-Based Method (S.R. Correa, L. G. Shapiro, M. Melia, 2001)

Each method has advantages and disadvantages for matching 3D objects. In this work we present our novel method which works based on ICP. The reason behind ICP is that more easier than other methods also much faster than others. It can be implement any kind of systems or 3D object to work on. Following chapters we show that ICP can be used not only aligning two 3D object also can be used for partial or complete 3D object matching and recognizing. Also we evaluated the performance and robustness of ICP.

3 3D POINT CLOUD DATA

3.1 What is Point Cloud ?

A point cloud is a set of data points which can be on 2D, 3D or more coordinate system. Figure 3.1 show an example of point cloud image. It also contains information about point's face. For example in a 3D coordinate system, data points represent X, Y, Z and often are intended to represent the external surface of an object.

Nowadays point clouds can be easily created by 3D scanners such as Leica, LiDAR, Microsoft Kinect. There are many purpose to have a point cloud data for example to create 3D models for manufactured parts, cultural heritage, medical purposes, and a multitude of visualization, animation, rendering and mass customization applications.

However point clouds have information about objects. They are not usable for many application so point clouds can be converted to a 3D surface by using Delaunay triangulation, alpha shapes, and ball pivoting, build a network of triangles over the existing vertices of the point cloud, while other approaches convert the point cloud into a volumetric distance field and reconstruct the implicit surface so defined through a marching cubes algorithm.

Figure 3.1 A point cloud image of a torus.

3.2 Saltanat Gate

Dolmabahçe Palace was built by Sultan Abdulmecid (1839-1861) who was the thirty first Ottoman Sultan. The palace, whose construction commenced on June 13th, 1843, was brought into use on June 7th, 1856, upon completion of surrounding walls. The palace mainly consists of three parts, named as the Imperial Mabeyn (State Apartments), Muayede Salon (Ceremonial Hall) and the Imperial Harem. Saltanat Gate locates at Muayede Salon.

We used Leica laser scanner to get 3D points data of Saltanat Gate. This scanner able to scan 270 degree horizontally and 360 degree vertically and get up to 500,000 points/sec. To complete whole Saltanat Gate we put the scanner different locations. Figure 3.2 shows that where we located and scanned the gate.

Figure 3.2 shows the location of scanning places and scanning rate.

Figure 3.3 shows that how it looks like all scan completed and aligned.

After getting the 3D points data as ptx format we converted them into ply format by using Leica Cyclone software. Ply is a format for storing graphical objects that are described as a collection of

polygons which is much more easy to handle and friendly format to other software such as MAYA, Blender, Meshlab.

Figure 3.6 Close lookup 3D point clouds of Saltanat Gate which was scanned from just one position

4 3D OBJECT RECOGNITION BY USING ICP

Object recognition is the ability to perceive an object's physical properties (such as shape, colour and texture) and apply semantic attributes to the object, which includes the understanding of its use, previous experience with the object and how it relates to others. (Enns, J. T., 2004)

4.1 What is ICP ?

The ICP Algorithm was developed by Besl and McKay (P. Besl and N. McKay, 1992) and is usually used to register two given point sets in a common coordinate system. The algorithm calculates iteratively the registration. In each iteration step, the algorithm selects the closest points as correspondences and calculates the transformation, i.e., rotation and translation (R,t), for minimizing the equation

$$E(R, t) = \sum_{i=1}^{N_m} \sum_{j=1}^{N_d} w_{i,j} \|m_i - (Rd_j + t)\|^2$$

where N_m and N_d , are the number of points in the model set M and data set D, respectively, and $w_{i,j}$ are the weights for a point match. The weights are assigned as follows: $w_{i,j} = 1$, if m_i is the closest point to d_j , $w_{i,j} = 0$ otherwise. Equation can be reduced to

$$E(R, t) \propto \frac{1}{N} \sum_{j=1}^N \|m_i - (Rd_j + t)\|^2$$

with

$$N = \sum_{i=1}^{N_m} \sum_{j=1}^{N_d} w_{i,j}$$

,since the correspondence matrix can be represented by a vector v containing the point pairs, i.e.,

$v = (d_1, m_{f(d_1)}), (d_2, m_{f(d_2)}), \dots, (d_{N_d}, m_{f(d_{N_d})})$, with $f(x)$ the search function returning the closest point. The assumption is that in the last iteration step the point correspondences, thus the vector of point pairs, are correct.

In each ICP iteration, the transformation can be calculated based on these four methods: A singular value decomposition based method of Arun et al. (K. S. Arun, T. S. Huang, and S. D. Blostein, 1987) a quaternion method of Horn (B. K. P. Horn, 1987), an algorithm using orthonormal matrices of Horn et al. (B.K. P. Horn, H. M. Hilden, et al., 1988) and a calculation based on dual quaternions of Walker et al. (M. W. Walker, L. Shao, and R. A. Volz, 1991). These algorithms show similar performance on noisy data (A. Lorusso, D. Eggert, and R. Fisher, 1995).

Arun et al. observed that “the computer time requirements for the SVD and (unit) quaternion algorithms are comparable” (B. K. P. Horn, 1987). In a paper not directly related to any of the methods, Zhang implemented both of the quaternion algorithms and found that “they yield exactly the same motion estimate” (B. K. P. Horn, 1987). Also, he found these two techniques to be more efficient than an iterative technique based on the extended Kalman filter that he developed. Finally, Walker et al. stated that “the two algorithms produce the same rotation errors for the translation errors, the DQ algorithm exhibits better performance than the SVD algorithm” (M. W. Walker, L. Shao, and R. A. Volz, 1991). The thorough and unbiased comparison presented here will clarify, extend (and even refute) some of these previous findings

4.2 Using ICP on 3D Data

ICP based on finding minimal distances between closest points and then rotates and transforms the data thus this methods takes long time work on huge data such as Salanat Gate which has 2770070 points. Instead of working huge data it is better of slice the data and then work on it. One of the big consideration is to divide 3D point clouds data. Because as we worked on ply file format we did not know how our looking object locates on 3D point cloud. It is not important as long as we slice the 3D point cloud correctly because ICP is not affected by rotation or transformation but How can be sure of that we sliced correctly? First we decided to display our 3D scanned point cloud. Earlier ICP method did not give good results because we sliced it wrong. Figure 4.1 and Figure 4.2 shows that how we previously sliced 3D point cloud object that led us wrong object matching and object recognition.

Figure 4.1 shows that how we sliced the object based on X axes

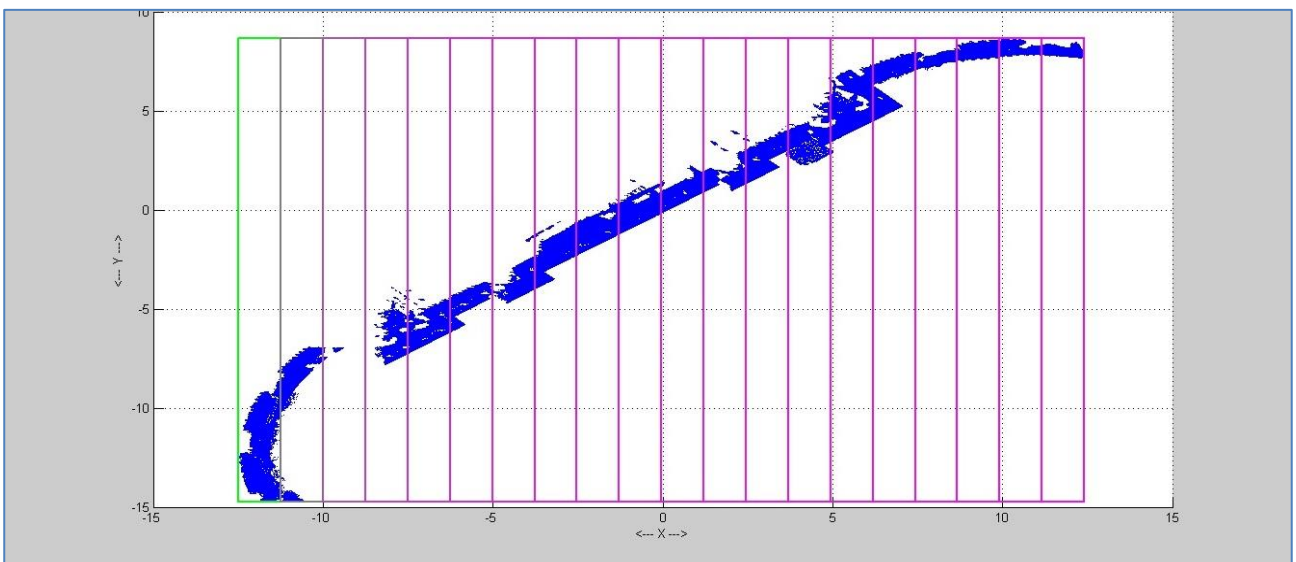

Figure 4.2 shows top view of how we sliced the object based on X axes

The 3D point cloud data must be rotated as same as desired object. There are too many methods to rotate the object. M. Chaouch, A. Verroust's (M. Chaouch, A. Verroust, 2008) method is one of best automated alligmented method for desired results. It also possible to rotate and tranform the object by using Meshlab, Maya, ... etc. After rotating the object is ready to recognize for desired 3D object Figure 4.4. First step is dividing the 3D point cloud data as close as desired object. Main reason for dividing 3D point cloud to sub points clouds is to get good results and save the time. We

divided 3D point cloud data as 20 horizontally Figure 4.4 and 20 vertically Figure 4.7 such as 400 sub point clouds. To be safe side we decided to divide big as each sub point cloud at least 3 times bigger than the looking 3D object.

Figure 4.3 This object one part of Saltanat Gate which is desired object. This object as small as approximately 1/1200 of Saltanat Gate.

Figure 4.4 horizontally dividing into 20 sub point clouds.

Figure 4.5 close look up of horizontally divided sub point clouds.

Figure 4.6 Checking desired object to make sure it is not divide by our method.

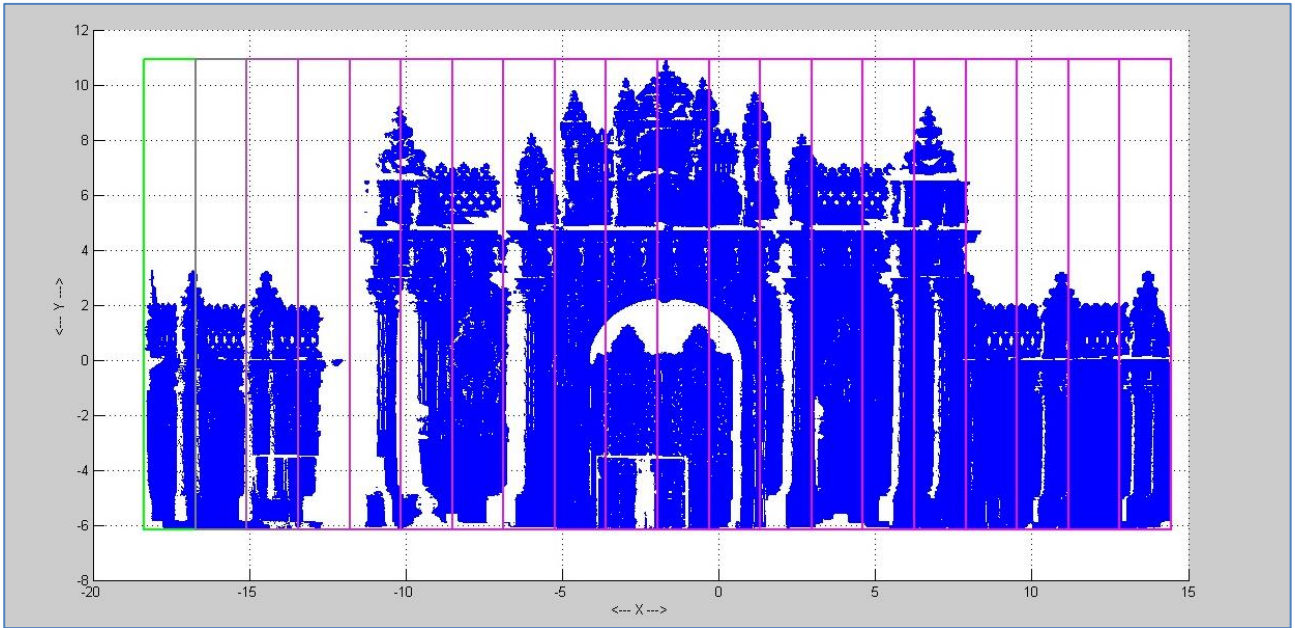

Figure 4.7 vertically dividing into 20 sub point clouds.

Figure 4.8 close look up of horizontally divided sub point clouds.

After slicing vertically and horizontally the data (Saltanat Gate) turn into small pieces close to desired object.

Figure 4.9 Now it is ready to apply ICP [Figure 4.4] on each small pieces.

The algorithm of our ICP is shown below;

Algorithm : ICP

Input: Reference 3D point cloud or 3D object P and input 3D point cloud or 3D object X

Output : Registration result of X and iteration number

Intialization: Set iteration number $k=0$, maximum iteration numeber to N, ICP convergence tolerance τ and stoping threshold th_ϵ for the whole process, R^0 and t^0 are set by Principle Compenent Analysis, invariant feature point extraction threshold th_M and increment Δth_M

1st Find the corresponding between P and X with the transformation (R^k, t^k)

2nd Compute mean square error $\overline{d_k}$ of the corresponding points between P and X

3rd **While** ($\overline{d_k} > th_\epsilon$ and $k < N$)

4th **While** ($\overline{d_k} > \overline{d_{k-1}} > \tau$)

5th Find the corresponding between P and X with the transformation (R^k, t^k)

6th Apply transformation (R^k, t^k) to the (k-1)th input data X_{k-1} , then
 $X_k = R^k, X_{k-1} + t^k$

7th **end while**

8th Set $th_M = th_M - \Delta th_M$

9th **end while**

Figure 4.10 shows that how ICP algorithm works on our designed system.

After getting the result of distances for each pieces Table A.1. we choosed the closest top three divisions based on average incerasing rate of iteration. The reason of chosen top three increasing rated division is that every iteration two compared piece getting closer which means they have

higher approach rate Table A.2. After selecting top three divisions now we compared which one getting closer to desired object. Figure 4.10

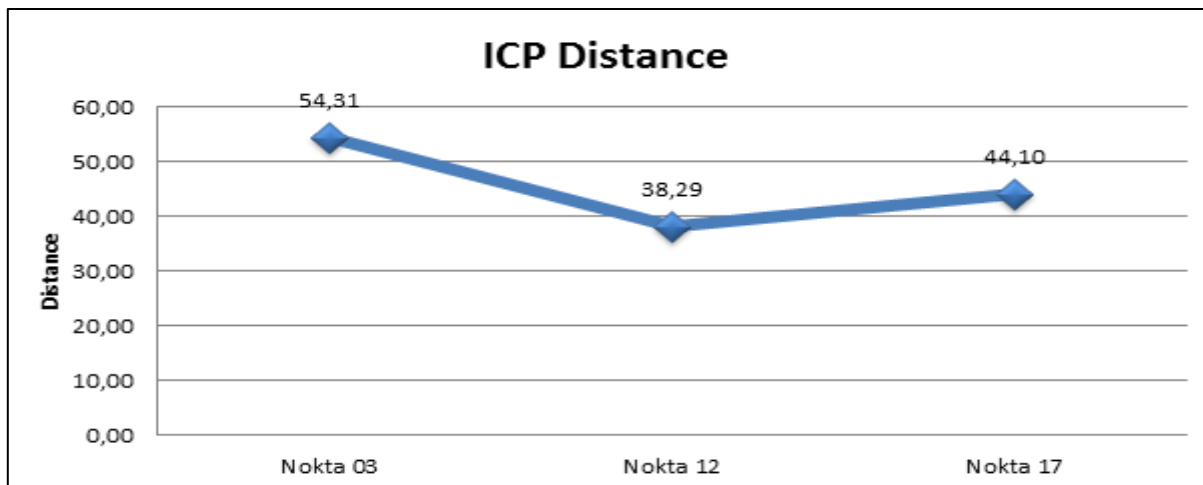

Figure 4.11. shows Nokta 12 division has minimum distance to desired object

Therefore we found best division to work on it. To see better result we sliced the divisions close as our compared object approximately one of third.

The result satisfies us because we did not remove noisy point on our Saltanat Gate or sliced same size as desired object also we used brute force method ICP (root mean square). However in recent years different strategies for point reduction, i.e., point selection, matching and weighting have been proposed and evaluated ([S. Rusinkiewicz and M. Levoy, 2001) Rusinkiewicz and Levoy propose a high speed ICP variant using a point-to-plane error metric (P. Neugebauer, 1997) and a projection-based method to generate point correspondences ([G. Blais and D. Levine, 1995). Furthermore they conclude that the other stages of the ICP process appear to have little effect of convergence rate, so that they choose the simplest ones, namely random sampling, constant weighting, and a distance threshold for rejecting point pairs ([S. Rusinkiewicz and M. Levoy. 2001). or Sparse Iterative Closest Point (S. Bouaziz, A. Tagliasacchi and M. Pauly, 2013) which excludes outliers and missing parts of data on object and gives superior registration results when dealing with outliers and incomplete data. However our result good as developed ICPs. We get almost exact matching. Our desired object as close as 0.08133 to sliced part of Saltanat Gate and we got this result by trying 50 iteration in 6.1 second (After fifth iteration it is not necessary to iterate) Figure 4.12. By this way we found where desired object locates on Saltanat Gate. The part we worked on it locates 12nd horizontally sliced pieces 13rd vertically sliced pieces and first parts of this piece.

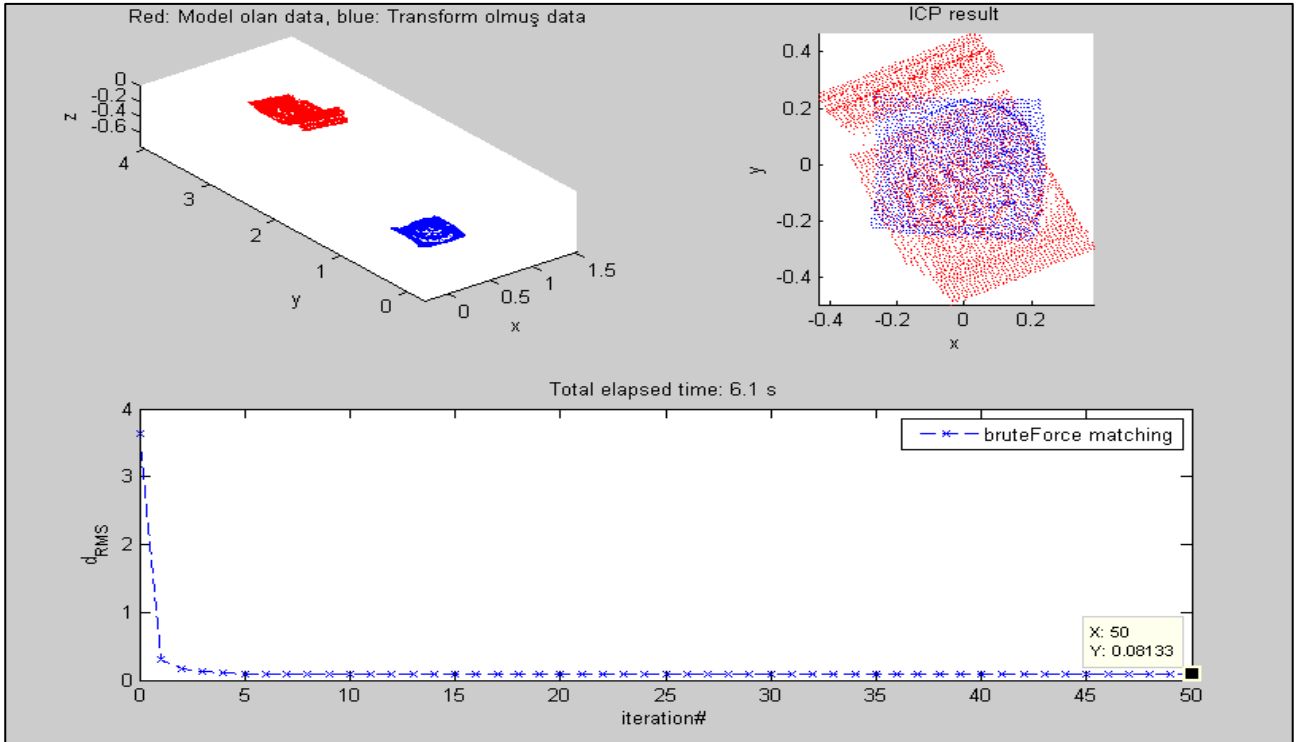

Figure 4.12 shows that iteration number, time, distance of two objects, locations of two objects before ICP apply on it also after it.

5 EXPERIMENTAL STUDY

For our experiments of ICP, we used a computer running on Windows8 64bit operating system, having 16GB of main memory and having Intel I7 3630QM 2.4 GHz processor. We also used Matlab R2013 to implement our ICP and showing results, also MAYA, Meshlab, Leica Cyclone to handle the point cloud data.

We evaluated our ICP method 4 different objects Figure 5.1 to show its efficiency and applicability on different objects. Some objects are available in The Stanford 3D Scanning Repository. To give small information about object, every object has different size, vertex, face and scanned angle. Table 5.1 Some objects are incomplete which scanned form one angle others are completed.

Object Name	Number of Vertex	Number of Face	View	Completed Object
Armadillo	169016	335506	Front	Not
Bunny	40256	79312	Top	Not
Business Jet	6367	12702	Diagonal	Yes
Cow	2903	5804	Front	Yes

Table 5.1 shows properties of 3D objects

5.1 Efficiency

We started with choosing a 3D object which sliced from whole 3D object to recognize in the whole 3D object. Figure 5.1 shows which models was used to evaluate our ICP to recognize 3D object.

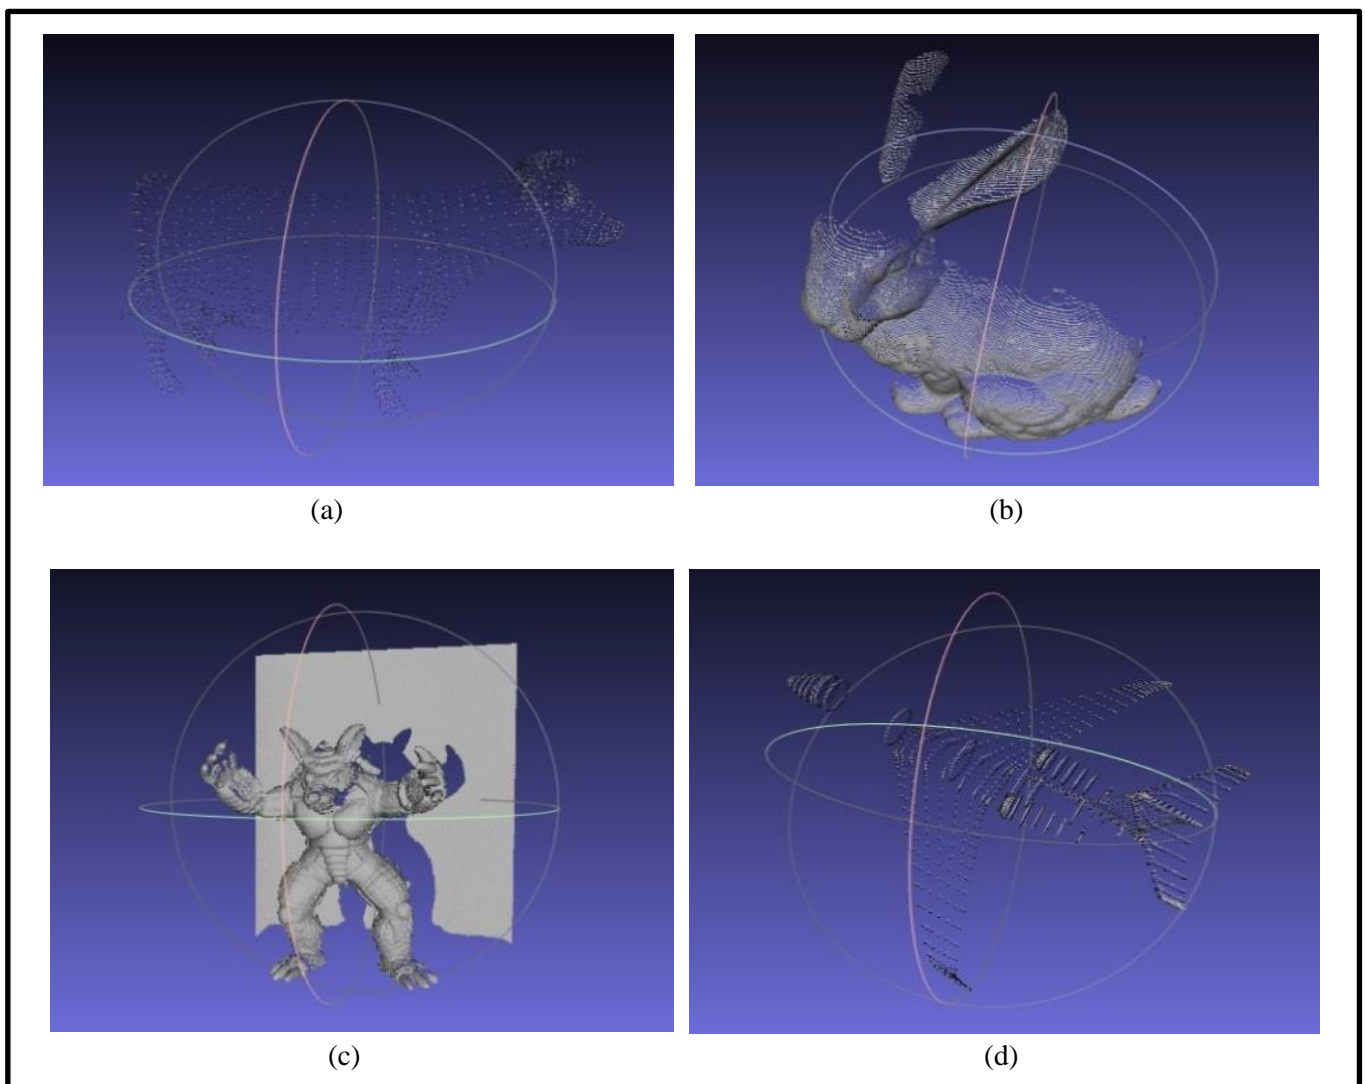

Figure 5.1 shows 3D objects which was used to evaluate our ICP method, (a) is a cow, (b) is a bunny, (c) is an Armadillo and (d) is a jet.

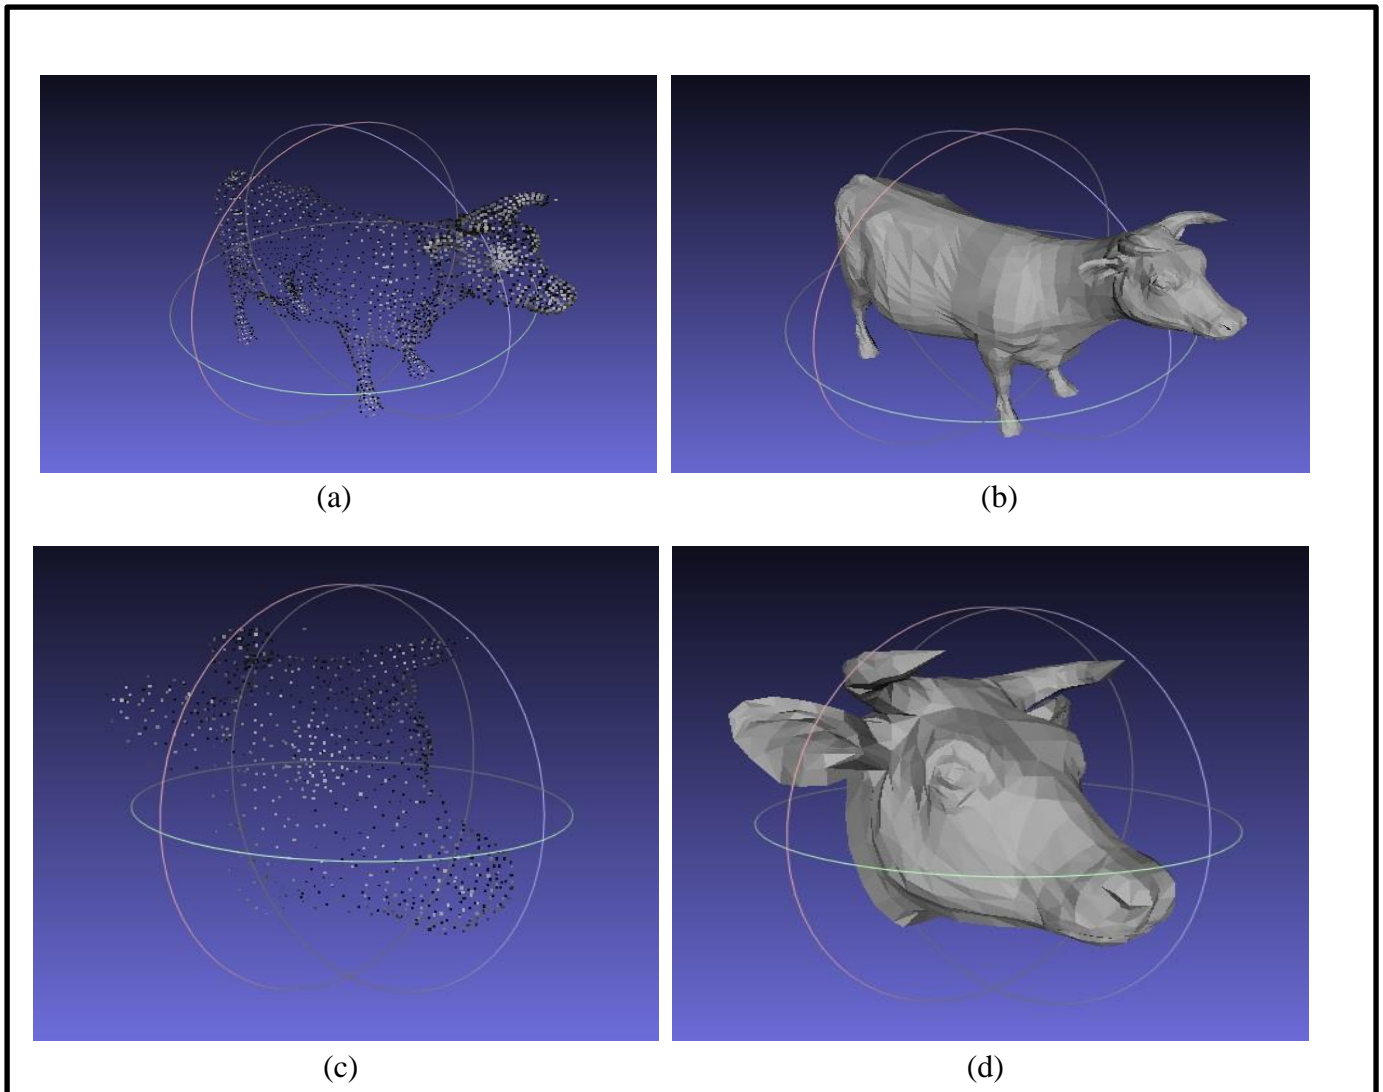

Figure 5.2 (a) is points view of whole 3D object. (b) is falted view of the 3D object. (c) is points view of part of the 3D object which is used for recognizing on the 3D object (d) is falted view of the 3D object.

As usual our approach we first divided the completed cow data as close as cow's head or desired 3D object.

Figure 5.3 shows how looks like when we divided Cow as close as Cow's head. In this case we divided 4 pieces based on X axis.

Process time of recognizing the object is 6 seconds. The ICP is really fast and we have exact match on last division of cow data. Figure A.3 and Table 5.2 shows results of ICP

Division Number	Number of Iterate	Distance
Nokta1	83	19.5824
Nokta2	18	81.6433
Nokta3	62	37.2276
Nokta4	27	0.0001

Table 5.2 shows number of iteration and closest distances between two 3D objects for Cow.

Figure A.3. shows how our ICP method matches two 3D object. The figures are organized by first location of two object and then location after ICP. The figures are consist of two symbol which are first object is represent by "o" symbol the second object represent by "x" symbol.

To challenge we chosed Bunny which is more complicated 3D object than Cow which uncompleted object also has noisy points on 3D object. To push the limit we chosed bunny's head for being medium size object. We also rotated the bunny's head from orginal location to see result of ICP.

Figure 5.4 (a) is points view of whole 3D object. (b) is falsted view of the 3D object. (c) is points view of part of the 3D object which is used for recognizing on the 3D object (d) is falsted view of the 3D object.

Figure 5.5 shows how looks like when we divided Bunny as close as Bunny's head. In this case we divided 3 pieces based on X axis. After that we divided 2 pieces based on Y axis.

Process time of recognizing the object is 23 seconds. The ICP is really fast and we have exact match on second sub cloud division of bunny data. Figure A.6 and Table 5.5 shows results of ICP so according to bunny case rotating the object has minor effect on recognizing the object.

Next scenario is moving part of object and then try to recognize where the object belong. So we decided to choose Jet and make it interesting we purposely chose the jet motor and we expect that we find two closest object matching.

Figure 5.6 (a) is points view of whole 3D object. (b) is faltd view of the 3D object. (c) is points view of part of the 3D object which is used for recognizing on the 3D object (d) is faltd view of the 3D object.

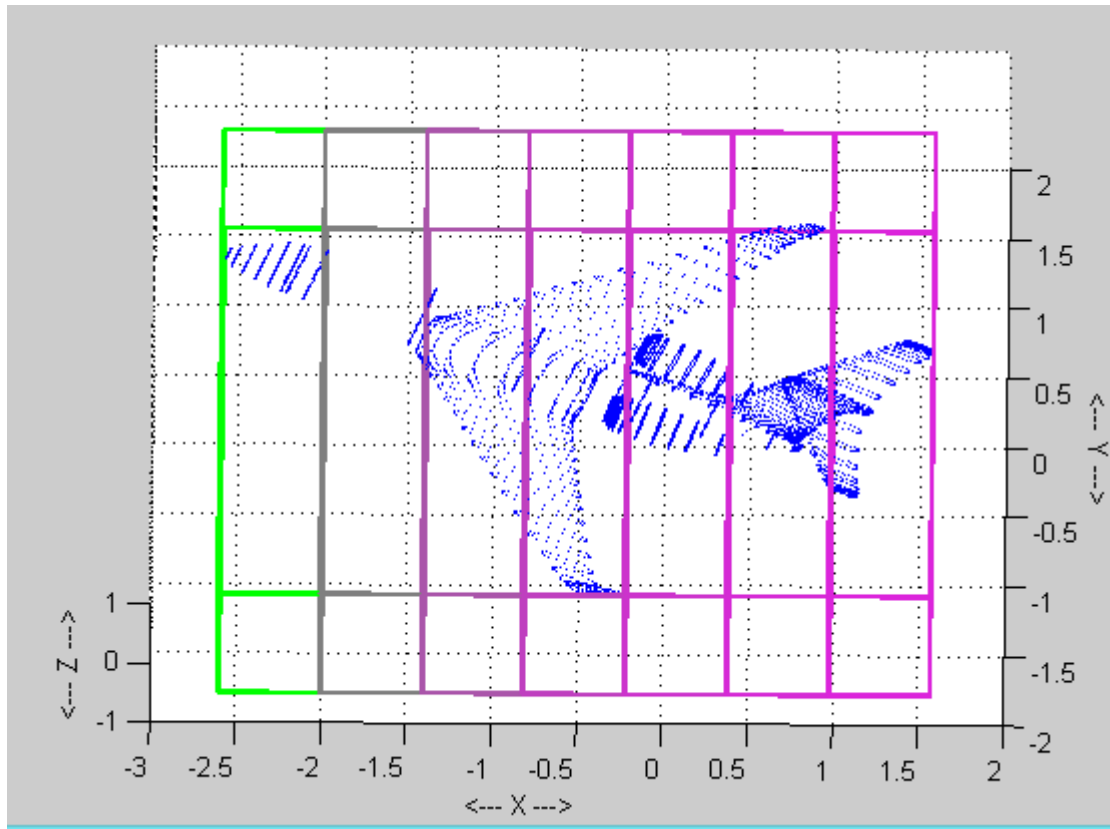

Figure 5.7 shows how looks like when we divided Jet as close as Jet's motor. In this case we divided 7 pieces based on X axis. After that we divided 5 pieces based on Y axis. The object itself is rotated.

Even though we had the smallest distance between two point clouds object shown in Table A.6 . It does not mean that we found the desired object. Because the noisy data always have fatal error on the result Figure A.7 and Figure A.8. To discard the noisy data affect on the results we have to slice the object small as the jet motor or have to find outliers on each sub cloud and exclude the outliers. However our ICP method reyls on simplest matching algorithm so we have to slice it as much as possible. Therefore we sliced 10 pieces based on Y axis and

Figure 5.8 we divided 10 pieces based on y axis. After that we divided 7 pieces based on x axis.

Even though we got good result Table A.7 we could not get rid of noisy data affect. There we can understand our ICP method has weakness to noisy data.

To challenge we chosed much more complicated 3D Object which uncompeleted object also has noisy points on 3D object which is Armadillo. To make it interesting we chosed very small part of the Object which is left leg. We also moved and rotated the leg from original direction.

(a)

(b)

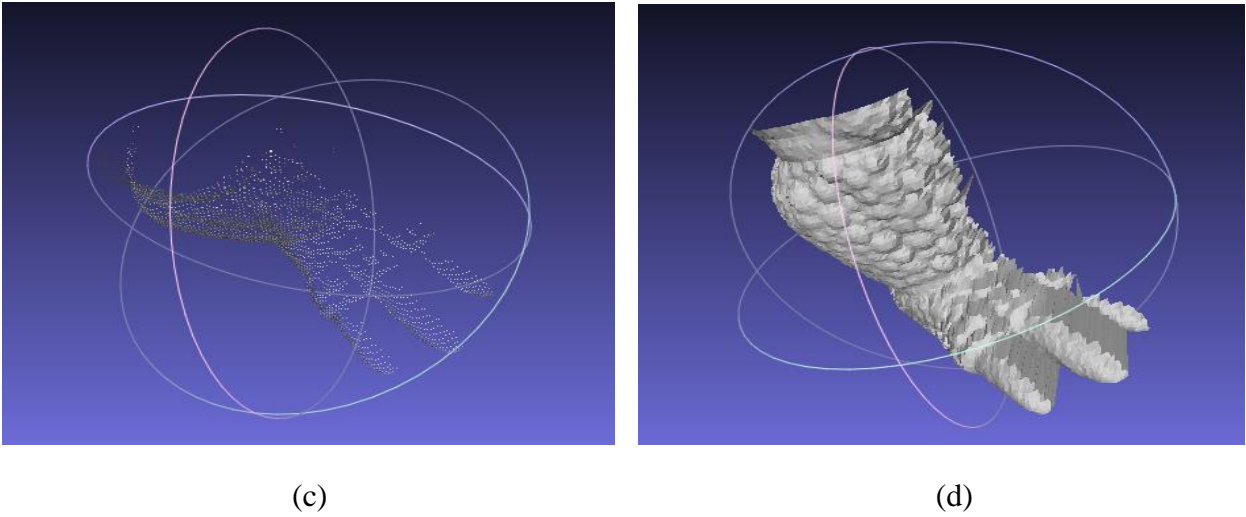

Figure 5.9 (a) is points view of whole 3D object. (b) is faltd view of the 3D object. (c) is points view of part of the 3D object which is used for recognizing on the 3D object (d) is faltd view of the 3D object.

As usual our approach we first divided the compleeted Armadillo data as close as Armadillo's left leg or desired 3D object. Figure 5.5 also shows that there are too many noisy point on 3D object.

Figure 5.10 shows how looks like when we divided Armadillo as close as Armadillo's left leg. In this case we divided 4 pieces based on Y axis.

Lets see how it responses only based on slicing Y axis it is actually conflict our method however we want to show the results of it. Figure A.5. shows that size is really essential for our ICP method. According to Table 5.3. none of iteration gives close matching result.

Division Number	Number of Iterate	Distance
Nokta1	20	0,16307
Nokta2	23	0,35163
Nokta3	41	0,22765
Nokta4	439	0,64425

Table 5.3 shows number of iteration and closest distances between two 3D objects for Armadillo.

Slicing the object just base on Y axis is not enough so we have divided base on X axis. It is essential to consider X,Y,Z when you working on 3D object.

Figure 5.11 shows how looks like when we divided Armadillo as close as Armadillo's left leg. In this case we divided 8 pieces based on X axis.

We purposely sliced the whole 3D data which does not contain completed desired object in any sub cloud. We purposely put some part of desired object in a sub cloud other parts located other sub clouds. The reason behind it that is we want to evaluate our approach of average increasing rate of iteration that have any connection to desired recognized object. According to Table A.4. we could understand the desired object locates one of them. We could recognize the object by increasing or decreasing number of sub cloud and then progress same as Saltanat Gate.

5.2 Robustness

ICP works based on closest point even so if the closest points match exactly to each other it does not mean that rest of points will be matched. Thus just using Euclidean distance on ICP is not enough. Adjustment is essential for ICP specially for the closest point. Also to choose which points are closed it takes too much time to decide and calculate for each point. This makes too much consumption of CPU, Ram.

Also the problem of registering point clouds with outliers including noises and missing data makes ICP less reliable.

6 CONCLUSION

ICP based on finding minimal distances between closest points and then rotates and transforms the data until two object got enough closed. As we work on ICP method we able to recognize a part of object on completed object. ICP really works well on well defined 3D object which has no outliers or hole on 3D objects. ICP is affected by false matching, noise also size which is compared between two 3D objects. To get better result on ICP method, first make sure all outliers excluded from object also the object sliced close to compared object.

According to our study ICP works based on comparing distances between closest point so basically comparing each point to find which point is the closest makes our algorithm slow. For future work, ICP can be implement faster by finding new methods which reduce the time of comparing the closest points also can be focused on the stability and robustness of ICP. In addition, a better

analysis of the effects of various kinds of noise and distortion would yield further insights into the best alignment algorithms for real-world, noisy scanned data. Algorithms that switch between variants, depending on the local error landscape and the probable presence of local minima, might also provide increased robustness.
