*To my family,*

## **FOREWORD**

I would like to express my gratitude to Prof. Dr. Ercan Yüksel for his invaluable support and attention in the course of completing this study. It has been a great pleasure to study with him.

I would like to thank Dr. Melih Sürmeli for sharing his knowledge and experiences with me, taking time and showing all kinds of support during my graduate education, like in my undergraduate education.

Finally, I am grateful to my family for their effort and support in my life.

December 2019

Özge OSMAK

## LIST OF SYMBOLS

$d_b$	: Bar diameter
$D_n$	: Displacement vector for $n^{th}$ mode
$D_{mn}$	: Target displacement demand at the $m^{th}$ DOF for $n^{th}$ mode
$D_{mn\_g}$	: The displacement demand at the $m^{th}$ DOF due to gravity loading
$D_{mn\_gx}, D_{mn\_gy}$	: The displacement demands in X and Y directions at the $m^{th}$ DOF due to gravity loading
$D_{mn\_g\theta}$	: The displacement demand in $\theta_z$ direction at the $m^{th}$ DOF due to gravity loading
$D_{mn\_x}, D_{mn\_y}$	: Target displacement demand in x and y directions at the $m^{th}$ DOF for $n^{th}$ mode
$D_{mn\_theta}$	: Target displacement demand in $\theta_z$ direction at the $m^{th}$ DOF for $n^{th}$ mode
$E$	: Modulus of elasticity
$E_s$	: Modulus of elasticity for steel
$E_c$	: Modulus of elasticity for concrete
$EI$	: Flexural rigidity
$I$	: Moment of Inertia
$f_c$	: Expected compressive strength of concrete
$f_y$	: Expected yield strength of steel
$f_{y,eq}$	: Equivalent yield strength of beam bars.
$f_{ck}$	: Characteristic concrete compressive strength
$f_{yk}$	: Characteristic yield strength of steel
$G$	: Gravity load
$l_{b,av}$	: Available anchorage length
$l_{b,req}$	: Anchorage length required for full bar anchorage
$L_k$	: Short length of slab
$L_u$	: Long length of slab
$M$	: Mass matrix for 3D structural systems
$M_i, M_j$	: Bending moments at member ends
$M_p$	: Moment capacity
$P_0$	: System loading vector
$P_{0n}$	: System loading vector for $n^{th}$ mode
$Q$	: Live load
$Q_{0n}$	: $n^{th}$ mode compatible force vector obtained from elastic spectral accelerations
$Q_n$	: Nodal force vector which provides target displacement at the reference DOF for $n^{th}$ mode
$R$	: Demand parameter of interest

$R_g$	: Demand parameter of interest obtained from gravity loads
$R_n$	: Demand parameter of interest for the $n^{th}$ mode
$R_{n+g}$	: Demand parameter of interest obtained from $n^{th}$ mode horizontal force vectors and gravity loads
$s_n$	: The $n^{th}$ mode contribution of effective earthquake force vectors
$s_{nx}, s_{ny}$	: The $n^{th}$ mode contribution of effective earthquake force vectors for the two horizontal components of ground motion
$S_{an\_e}$	: Elastic spectral acceleration for $n^{th}$ mode
$S_{an\_ex}$	: Elastic spectral acceleration of x directional earthquake for $n^{th}$ mode
$S_{an\_ey}$	: Elastic spectral acceleration of y directional earthquake for $n^{th}$ mode
$S_{an\_px}$	: Plastic spectral acceleration of x directional earthquake for $n^{th}$ mode
$S_{an\_py}$	: Plastic spectral acceleration of y directional earthquake for $n^{th}$ mode
$S_n$	: System stiffness matrix for $n^{th}$ mode
$\ddot{u}_{gx}, \ddot{u}_{gy}$	: Horizontal acceleration components of ground motion
$W_p$	: Plastic section modulus
$X, Y, Z$	: Global axis system
$\Gamma_{nx}, \Gamma_{ny}$	: Modal participation factor of $n^{th}$ mode for the X and Y components of ground motion
$\sigma$	: Stress
$\sigma_c$	: Concrete stress
$\sigma_y$	: Yield stress of steel
$\phi_p$	: Curvature corresponding to $M_p$
$\alpha_n$	: The loading parameter for $n^{th}$ mode

# **THE ASSESSMENT OF THE VARIANT MODAL PUSHOVER ANALYSIS PROCEDURE FOR SPECIFIC BUILDINGS SUBJECTED TO BIDIRECTIONAL GROUND MOTIONS**

## **SUMMARY**

In this study, variant modal pushover analysis (VMPA) and adaptive version of VMPA (VMPA-A) were applied to evaluate the earthquake performance of asymmetric- plan buildings and high-rise buildings. These methods were implemented through MATLAB based computer programme known as DOC3D software. The 3-storey SPEAR building and the 20-storey SAC building, which are frequently used in the literature, were used as benchmark structures.

Two different approaches to estimate the displacement demands for each mode were applied. The first one is calculation of displacement demand directly from elastic spectral acceleration by using equal displacement rule. In the second approach, mode compatible force vectors are applied to structure and capacity curves of each mode is created. By converting capacity curves to modal pseudo acceleration-displacement relations, the modal capacity curves are obtained. Nonlinear time history analysis (NTHA) is performed to each modal single degree of freedom system (SDOF) and the displacement demands are calculated. The obtained results calculated from the two approaches were compared with Nonlinear Time History Analysis (NTHA) results which was performed by SAP2000 software.

In these verifications, different earthquake record groups were used for each structure. The first group of records for the SPEAR building includes 7 earthquakes from literature. The second for the 20-storey SAC building includes 14 earthquakes from the PEER NGA database. The compared parameters are storey shears, storey displacements, story drifts, column and beam curvatures.

Bi-directional ground motions are taken into account in the VMPA and VMPA-A methods by using hybrid spectrum concept, whose abscissas and ordinates are named as  $\Gamma_{nx} S_{dx} + \Gamma_{ny} S_{dy}$  and  $\Gamma_{nx} S_{ax} + \Gamma_{ny} S_{ay}$ , respectively. As in the  $S_d$ -  $S_a$  relationship, the slope of this hybrid spectrum corresponding to a given period is equal to the square of

the angular frequency of the respective period. Thus, two horizontal component of ground motions can be considered together with the help of this spectrum.

# İKİ DOĞRULTUDA YER HAREKETİNE MARUZ KALAN ÖZEL BİNALAR İÇİN DEĞİŞTİRİLMİŞ MODAL İTME ANALİZİ PROSEDÜRÜNÜN DEĞERLENDİRİLMESİ

## ÖZET

Bu çalışmada, planda düzensiz ve yüksek binaların deprem performanslarını değerlendirmek üzere değiştirilmiş modal itme analizi (VMPA) ile yöntemin uyarlamalı versiyonu olan VMPA-A uygulanmıştır. Bu yöntemler MATLAB tabanlı DOC3D yazılımı vasıtasıyla uygulanmıştır. Literatürde sıkça kullanılan 3 katlı SPEAR binası ve 20 katlı SAC binası doğrulama örnekleri olarak kullanılmıştır.

Her bir mod için yerdeğiştirme taleplerini tahmin etmek için iki farklı yaklaşım kullanılmıştır. Bunlardan ilki eşit yerdeğiştirme kuralının uygulanması ile elastik spektral ivme spektrumundan yerdeğiştirme isteminin direkt olarak elde edilmesidir. İkinci yaklaşımda ise, taşıyıcı sisteme her bir titreşim modu ile uyumlu kuvvetler uygulanarak bu modlara ait kapasite eğrileri oluşturulur. Sonrasında kapasite eğrileri modal sözde ivme- yer değiştirme ilişkilerine dönüştürülerek her bir mod için modal kapasite eğrileri elde edilir. Dönüştürülmüş doğrusal olmayan tek serbestlik dereceli sistemlere uygulanan zaman tanım alanında analiz sonucu yerdeğiştirme talepleri hesaplanmaktadır. Her iki yaklaşımdan elde edilen bu sonuçlar SAP2000 yazılımı kullanılarak elde edilen doğrusal olmayan zaman tanım alanında analiz sonuçları ile karşılaştırılmıştır.

Bu doğrulamalarda, her yapı için farklı deprem kayıt grubu kullanılmıştır. SPEAR binası için olan ilk kayıt grubu literatürde yer alan 7 depremi içermektedir. 20 katlı SAC binası için olan ikincisi ise PEER NGA veri tabanından alınan 14 tarihsel depremi içermektedir. Analizler sonucunda karşılaştırılan büyüklükler kat ötelenmeleri, kat ötelenmeleri oranı, kat kesme kuvvetleri ve seçilen kolon ve kirişlerdeki eğrilik değerleridir.

VMPA ve VMPA-A yöntemlerinde çift doğrultuda etkiyen depremin dikkate alınması hibrit spektrum yardımıyla yapılmaktadır. Bu spektrumda apsis ve ordinatı sırasıyla  $\Gamma_{nx} S_{dx} + \Gamma_{ny} S_{dy}$  ve  $\Gamma_{nx} S_{ax} + \Gamma_{ny} S_{ay}$  şeklindedir.  $S_d$ -  $S_a$  ilişkisindeki gibi bu hibrit

spektrumunun belirli bir periyoda karşı gelen eğimi ilgili periyodun açısal frekansının karesine eşittir. Bu spektrum yardımıyla deprem hareketinin iki yatay bileşeni birlikte dikkate alınabilmektedir.

## 1. INTRODUCTION

Nonlinear Time History Analysis (NTHA) is most accurate method used in evaluation of seismic demands of the structure. However, NTHA is a complex and time-consuming process.

Nonlinear Static Procedure (NSP) is a conventional procedure used to determine seismic demands of the structure. An invariant lateral force distribution corresponding to fundamental mode shape is applied to structure. That's why, in high-rise buildings or asymmetric- plan buildings, NSPs are inadequate. So, the applicability of pushover analysis must be extended to structure which is affected by higher modes.

As a multi mode procedure, modal pushover analysis (MPA) (Goel and Chopra, 2005; Chopra and Goel, 2002, 2004a, 2004b; Chopra et al., 2004) is one of the most popular method to estimate seismic demands of structures whose higher modes are effective. In MPA, an invariant lateral force distribution is applied to structure in each mode to its modal target displacement. The response in each mode is combined by an appropriate modal combination rule to obtain overall building response. However, MPA has some shortcomings: 1) An invariant load pattern compatible with linear-elastic mode shape is applied to structure even though mode shapes change when the inelastic deformation increase. 2) The horizontal components of ground motion are considered separately. Some modal combination methods are used to combine the demand parameters or horizontal components of ground motions. The application of modal combination methods twice may cause errors in results. Several researchers have studied to extend the MPA procedure to overcome the shortcomings of MPA.

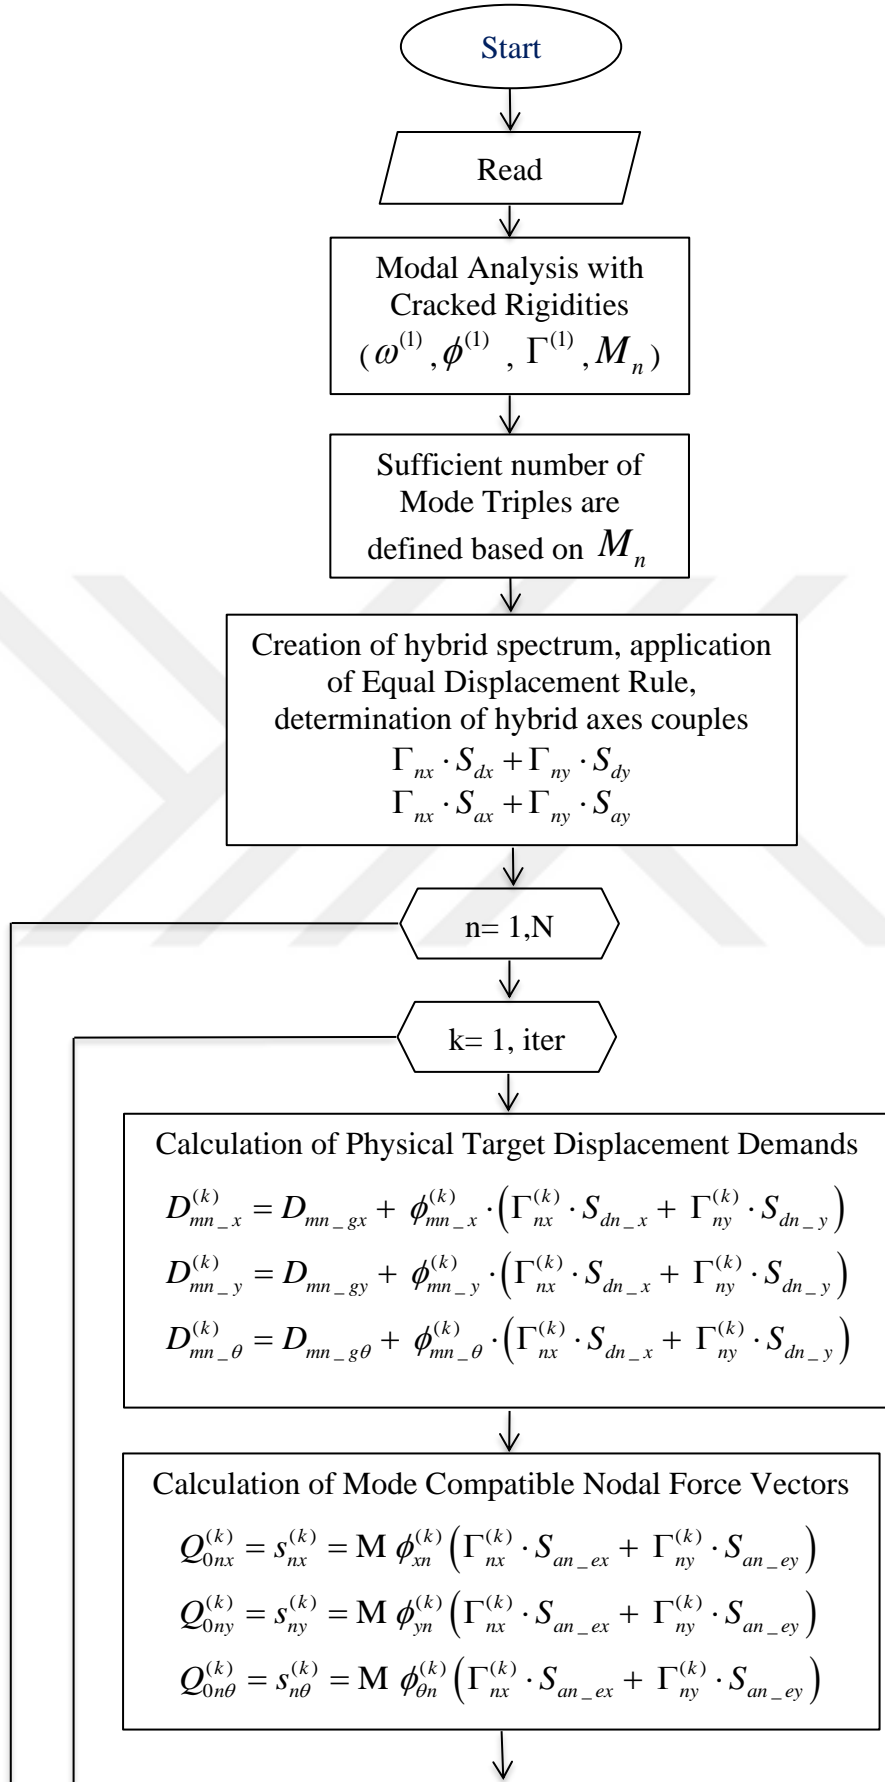

A Variant of Modal Pushover Analyses (VMPA) and adaptive version of VMPA (VMPA) have been proposed by Sürmeli and Yüksel (2015, 2018). In the adaptive version of VMPA procedure, lateral forces are recalculated at each iteration step due to the change in dynamic characteristics. The difference of VMPA from existing MPAs:

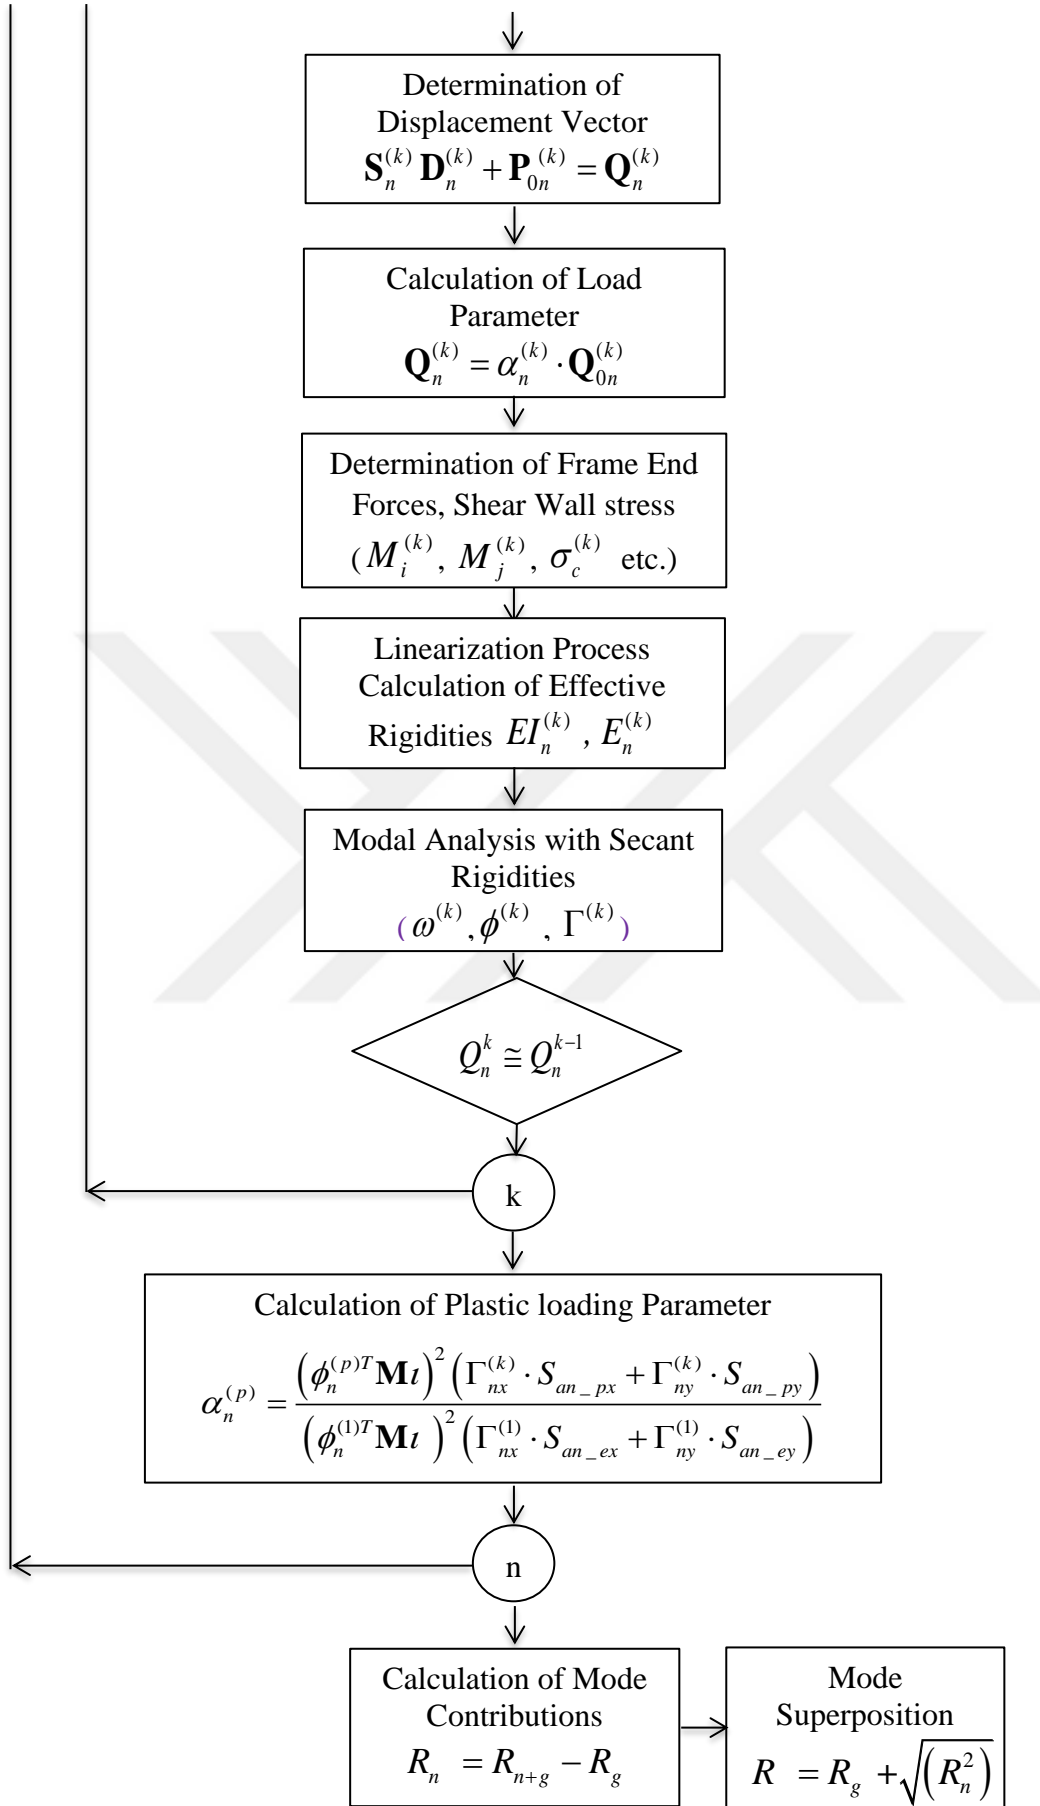

- mode compatible adaptive forces are applied to the structure at each iteration step
- bi-directional ground motions are considered with the hybrid spectrum concept. The methods of determination of seismic demands are applied together with secant stiffness based linearization in the spectral displacement ( $S_d$ ) – spectral acceleration ( $S_a$ ) relation. Therefore, the necessity of producing a modal capacity diagram for each mode is eliminated.

In the hybrid spectrum concept, whose abscissas and ordinates are named as  $\Gamma_{nx} S_{dx} + \Gamma_{ny} S_{dy}$  ve  $\Gamma_{nx} S_{ax} + \Gamma_{ny} S_{ay}$ , respectively, horizontal components of an earthquake record are considered simultaneously, and this concept provides a consistency between the force and displacement vectors for each mode. As in the  $S_d$ -  $S_a$  relationship, the slope of this hybrid spectrum corresponding to a given period is equal to the square of the angular frequency of the respective period.

In this study, VMPA and VMPA-A procedures are applied by using MATLAB based computer programme DOC3D. The flow-chart of the procedure is given in Figure 1.1. First of all, modal analysis are applied with cracked rigidities to obtain initial frequency ( $\omega^{(1)}$ ), mode shapes ( $\phi^{(1)}$ ), modal participation factors ( $\Gamma^{(1)}$ ) and modal mass participation ratios ( $M_n$ ). Then, sufficient number of mode triples are defined based on  $M_n$  (at least 90%) and hybrid spectrum are created for each mode triple. Mode compatible force vectors for each mode ( $Q_n^k$ ) are applied to the structure. Then secant based iteration process is began to tune the target displacement demands ( $D_{mn_x}, D_{mn_y}, D_{mn_\theta}$ ) until the force vectors obtained at consecutive steps are sufficiently close each other,  $Q_n^k \cong Q_n^{k-1}$ . Here,  $Q_n$  is compatible with the displacement vector. Finally, seismic demand obtained from each mode are combined by using SRSS combination method.

NTHA is applied by using SAP2000 software and results obtained is accepted as “exact solution” for this thesis.

**Figure 1.1:** Flow-chart of the proposed 3D Analysis Algorithm.

Two alternative methods were considered to estimate displacement demands of the structure. These are equal displacement rule and performing NTHA to modal SDOF.

The basic assumption of equal displacement rule is that the maximum inelastic deformation of a nonlinear single degree of freedom (SDOF) system is approximately equal to the maximum deformation of a linear- elastic SDOF system having the same stiffness as the initial stiffness of the inelastic system.

In the second approach, mode compatible force vectors are applied to structure and capacity of each mode is created. By converting capacity curves to modal pseudo acceleration-displacement relations, the modal capacity curves are obtained. Nonlinear time history analysis (NTHA) is performed to each modal single degree of freedom system (SDOF) and the displacement demands are calculated. In this study, NTHAs are performed to modal SDOF system by using SAP2000.

### **1.1 Aim of the Study**

Developing simple analysis methods with reasonable accuracy is increased in recent years due to complex and time-consuming process of NTHA. In this context, MPA, one of the main well-known pushover procedures, is considered as an alternative to NTHA. The method may be used for 3D structures under bidirectional earthquake loadings. The main deficiencies of MPA are the invariant force distribution and consideration of bidirectional earthquake loading as the component of separate unidirectional loadings. In this thesis, the variant of modal pushover analysis (VMPA) and the adaptive version of VMPA (VMPA-A) are implemented to analyze 3D asymmetric-plan building and high-rise building subjected to bidirectional ground motions.

## 2. LITERATURE

The Nonlinear Static Procedures (NSPs) are accepted as practical tools to estimate seismic demands in buildings. Different seismic codes such as ATC-40 (1996), CEN (2008), FEMA-356 (2000), FEMA-440 (2005), ASCE/SEI-41 (2007); recommend the implementation of NSPs to evaluate seismic performance of buildings. Two alternative methods are recommended in current standards to estimate the target displacement demand of the structure. These are the capacity spectrum method (ATC-40) and the displacement coefficient method (FEMA 356).

In NSPs, an invariant lateral force distribution corresponding to fundamental mode shape is applied to the structure. Therefore, the applicability of NSP is limited to low-rise buildings without torsional irregularities. Several researchers have studied to extend the applicability of pushover analysis to structure which is affected by higher modes (Antoniou and Pinho, 2004a, 2004b; Aydinoglu, 2003; Gupta and Kunnath, 2000; Kalkan and Kunnath, 2006).

MPA procedure is the most well known multi-mode pushover analysis method (Goel and Chopra, 2005; Chopra and Goel, 2002, 2004a, 2004b; Chopra et al., 2004). In this method, a lateral load pattern, which are appropriate with discrete mode shapes, is applied to structure for each mode. The predetermined seismic demand in each mode is combined by a modal combination rule to obtain displacement demand of structure.

A consecutive modal pushover procedure (CMP) is introduced by Poursha et al. (2009) for seismic evaluation of high-rise buildings. In this procedure, lateral load patterns appropriate with linear- elastic mode shapes are applied to structure consecutively. The procedure was also applied to asymmetric high-rise buildings by Poursha et al. (2011). Modified consecutive modal pushover analyses (MCMP) is proposed by Khoshnoudian and Kashani (2012).

Invariant force distribution is used in the multi-mode pushover analyses mentioned above. Since, the structural members of the building yield, the changes in the dynamic characteristics of the structure occurs. That's why, the lateral force distribution should

be modified in each step. Several adaptive modal pushover methods have been developed to consider the changes in dynamic characteristics. First adaptive modal pushover considers single mode behavior and this procedure is proposed by Bracci et al. (1997). In recent years, several researchers have studied on multi-mode adaptive pushover analysis. (Elnashi (2001), Aydınoğlu (2003,2004,2007), Antonio and Pinho (2004a, 2004b), Kalkan and Kunnath (2006), Shakeri et al. (2010, 2012), Abasnia et al. (2013) and, Sürmeli and Yüksel (2018). The multi-mode adaptive pushover methods can be classified into two groups as the first group, single-run pushover analysis and the second group, multi-run pushover analysis. In the first group, force or displacement distribution is calculated at each incremental step by combining mode contributions based on the instantaneous stiffness condition. In the second group, mode compatible force vectors is applied to structure separately, and the interested demand parameters are combined by an appropriate combination rule.

*Force-based adaptive pushover analysis* (FAP) was proposed by Elnashi (2001) and Antonio and Pinho (2004a) as a single-run pushover analysis. There is a shortcoming of FAP due to use of quadratic modal combination rule such as SRSS since the resulting forces are always positive at all story levels. To overcome this problem, *displacement-based adaptive pushover analysis* (DAP) was developed by Antonio and Pinho (2004b) as a modified version of FAP. In this procedure, the structure is subjected to displacements instead of forces. In this way, the sign reversal of forces at some story level is considered indirectly. When FAP and DAP procedures are compared, in predicting the earthquake demands, DAP procedure is more successful than FAP procedure (Antonio and Pinho 2004b). Another modified version of FAP, *a story shear-based adaptive pushover method* (SSAP) was developed by Shakeri et al. (2010). In the SSAP method, the structure is subjected to forces calculated by subtracting the instantaneous combined modal shear forces of the consecutive stories at each step. The implementation of the SSAP method to asymmetric-plan buildings was proposed by Shakeri et al. (2012). In this method, a lateral force in two translational directions and torques at each step are calculated by subtracting the combined modal storey shears and the combined modal story torques of consecutive storeys.

As a multi-run pushover analysis method, the adaptive modal combination (AMC) method was proposed by Kalkan and Kunnath (2006). This procedure derives its

fundamental shape from the adaptive pushover procedure of Gupta and Kunnath (2000). In the AMC method, the capacity spectrum method and the modal pushover procedure are combined without the necessity of the pre-estimation of target displacement. To estimate the dynamic target point, an energy-based methodology is utilized. In this methodology, inelastic displacement spectra with constant-ductility is used. Abbasnia et al. (2013) propose a displacement-based adaptive procedure based on the effective modal mass combination rule (APAM) to reverse the sign in the load vectors compatible with instantaneous mode shapes. In the estimation of target displacement, the method uses the same methodology with CSM and AMC. The load vector is scaled by relative mode contribution in the modal mass combination rule. The factor varies because of changes in dynamic characteristics. Modified load vectors are combined by summing/subtracting modified load vectors. Each combination is applied to the structure separately, and the envelope of the results is utilized. However, the interactions between the modes because of progressive yielding are not considered through the analysis process in both AMC and APAM methods.

Aydinoğlu (2003,2004, 2007) proposed an incremental response spectrum analysis (IRSA) procedure. In this procedure, a piece-wise linear incremental analysis procedure is conducted between formation of consecutive plastic hinges. Modal capacity diagram are used to estimate the modal inelastic demands as the backbone curves of modal hysteresis loops. The equal displacement rule with a smoothed elastic response spectrum was mentioned by Aydinoğlu (2003). It is a practical application of the method that uses a non-iterative pushover technique, and between two consecutive plastic hinges, linear analysis is applied using an instantaneous tangent stiffness matrix. Modal displacement or load patterns is applied to structure at each incremental pushover step for the unit value of an unknown incremental scale factor. In the calculation of the increment of the generic response quantity of interest, analysis of response spectrum is utilized. The resulting forces are obtained by adding the increments to previously obtained forces via incremental scale factor. After the calculation of the incremental scale factor of all potential plastic hinges, the smallest factor is chosen as an indicator of obtainment of the next plastic hinge. The other demand parameters are obtained by incremental scale factor.

The application of multi-mode NSPs on asymmetric-plan buildings has become significant in recent years (Chopra and Goel, 2004; Perus and Fajfar, 2005; Marusic

and Fajfar, 2005; Fajfar et al., 2005; Poursha et al., 2011; Kreslin and Fajfar, 2011, 2012; Shakeri et al., 2012). This application requires 3D pushover analysis to account torsional response of the buildings.

2D NTHA is recommended in the design of tall buildings in current tall-building design codes (SEAONC, 2007; LATBSDC, 2008; CTBUH, 2008; PEER, 2010). 3D multi-mode pushover procedures have been recently extended to estimate the seismic demand of buildings subjected to bidirectional ground motion. (Lin and Tsai, 2007, 2008; Reyes, 2009; Reyes and Chopra, 2011a, 2011b; Lin et al., 2012a, 2012b; Bosco et al., 2012, 2013; Manoukas et al., 2012, 2014; Poursha et al., 2014). MPA is one of the pioneering procedures which takes the influence of bidirectional ground motions (Reyes, 2009; Reyes and Chopra, 2011a, 2011b). However, there are two shortcomings of this procedure: 1) The structure is subjected to invariant load pattern compatible with the linear-elastic mode shape. The mode shapes and natural frequencies change when the inelastic deformations increase. When unidirectional ground motion is applied to asymmetric-plan buildings, deflection of the structure may not be only in the direction with the same as the direction of ground motion. It may also deflect in the perpendicular direction of ground motion and there could be rotations at the center of mass (CM). Therefore; for a selected node, three DOFs (namely, x and y translational and z rotational displacements) must be considered simultaneously in NSP procedure. Determining the displacements of three DOFs at the selected node simultaneously is not possible when the invariant load patterns are used. The dominant earthquake direction (x or y) of the building is selected as the target DOF by Reyes and Chopra (Reyes and Chopra, 2011a, 2011b). The building is pushed in this direction and the perpendicular direction is kept free. 2) The x and y components of the ground motion are considered separately in the MPA procedure. The demand parameters are combined by a CQC combination rule and an SRSS combination rule is used in the combination of two ground motion components. The combination methods are applied twice so, this may cause error in results. An equivalent single-DOF (E-DOF) system considering multi-directional seismic effects was established by Manoukas et al. (Manoukas et al., 2012, 2014). In this approach, x and y components of ground motion are accepted as proportional to each other with a scale factor ( $\ddot{u}_{gx} = \kappa \ddot{u}_{gy}$ ). Uniaxial pushover analysis is applied in two directions separately to avoid the erroneous results

because of the application of modal combination rule. Scale factor (SF) of  $\kappa$  is assumed as 0.3.

Three-DOF modal systems (representing two modal translations and one modal rotation) were developed by Lin and Tsai (2008) to assess the demands of two-way asymmetric building under bidirectional ground motion. Afterward, Lin and Tsai (2012a, 2012b) established inelastic response spectra which are constructed from the inelastic three-DOF modal systems.

A variant modal pushover analysis (VMPA) is proposed by Sürmeli and Yüksel (2018). In this procedure, bidirectional ground motion is considered simultaneously with hybrid spectrum concept, whose abscissas and ordinates are named as  $\Gamma_{nx} S_{dx} + \Gamma_{ny} S_{dy}$  ve  $\Gamma_{nx} S_{ax} + \Gamma_{ny} S_{ay}$ , respectively. In the hybrid spectrum concept, full modal capacity curve for each mode does not need to be obtained to determine seismic demands. The adaptive version of VMPA (VMPA-A) is also proposed by Sürmeli and Yüksel (2015, 2018). Change in the dynamic characteristics due to progressive yielding of the structural member is considered in this procedure.

### 3. CASE STUDIES

The 3-storey SPEAR building and the 20-storey SAC steel building, which are frequently used in the literature, were used as plan irregular and high-rise benchmark structures, respectively. The buildings are modeled with SAP2000 and DOC3D programmes. First of all, eigenvalue analyses are performed to provide the consistency between two programs. Secondly, pushovers analyses were conducted for fundamental modes at X and Y directions to calibrate the nonlinear behavior of the two programs. Finally, NTHAs, admitted as exact solutions, are performed by SAP2000 and the obtained demands are compared with those obtained by VMPA and VMPA-A procedures to investigate the accuracy of the methods.

#### 3.1 SPEAR Building (Plan Irregularity)

Spear building, a full-scale gravity load designed (GLD) building under pseudo dynamic conditions was tested, and subjected to bidirectional seismic loading, at the European Laboratory for Structural Assessment (ELSA) at Ispra, within the European project Seismic Performance Assessment and Rehabilitation (SPEAR) (Stratan and Fajfar, 2003). SPEAR building represents typical existing three-storey building that was designed for gravity loads alone, in the Mediterranean region. This structure was designed using Greece's concrete design code applying between 1954 and 1995, with construction practice and material used in the early 70's, Bhatt and Bento (2011).

The building has asymmetric plan in both X and Y direction and it is regular in elevation. The storey height of the structure is 3m, with 2.5m clear height and the slab thickness is 150mm. Plan and elevation view of the building is shown in Figure 3.1. Gravity loads (G) on slabs are  $0.5 \text{ kN/m}^2$  for finishings and  $2 \text{ kN/m}^2$  for live loads (Q).

The material properties, cross sectional dimensions, assumptions in modelling and hinge characteristics, the used earthquake records are taken from the study conducted by Stratan and Fajfar (2003).

**Figure 3.1:** Plan and elevation view of SPEAR building.

The building has 9 columns. Only the column C6 has rectangular section of 250x750 mm with strong direction along Y axis. The other columns have square section of 250x250 mm (Figure 3.2). Further details on the structure and column and beam sections can be found in Stratan and Fajfar (2003). The main reasons of the in-plan irregularities are presence of the balcony on the east side of the structure and column C6. Since the bigger dimension of C6 is in the Y direction, center of mass (CM) was shifted away from center of rigidity (CR) and larger eccentricity occurs in this direction. As shown in Figure 3.1, column C8 is at the *stiff edge*, while column C2 is the *flexible edge* of the building.

**Figure 3.2:** Typical column and beam cross-sections.

The confinement effects were ignored for core concrete, due to insufficient transverse reinforcement. The concrete was considered unconfined. The mean compressive strength of unconfined concrete was taken as 25 MPa ( $f_{ck}$ ) and design yield strength of steel reinforcement is 320 MPa ( $f_{yk}$ ). Strength degradation of concrete in compression and strain hardening of steel were considered. Expected material strengths are given in Table 3.1 and used for calculation of moment-curvature relations of members.

**Table 3.1:** Expected material strengths.

Concrete compression strength ( $f_c$ )	37.5 N/mm <sup>2</sup> (1.5 $f_{ck}$ )
Steel yield strength ( $f_y$ )	352 N/mm <sup>2</sup> (1.1 $f_{yk}$ )

### 3.1.1 Modelling of elements

The beams are modelled as T sections and effective widths ( $b_f$ ) are calculated. Since the effective widths at both ends of the beams are different, beams were divided into two parts. The subscript  $i$  corresponds to  $i^{\text{th}}$  part which is left side of the beams in X direction and bottom side of the beams in Y direction; while subscript  $j$  refers to the other part of the corresponding beams.

Because of inadequate construction practice and using of plain bars, insufficient anchorage of reinforcement was generated. In case, a procedure recommended in FEMA356 (2000), the yield strength of the bars is reduced proportionally to the ratio of available anchorage length to the one required for full anchorage:

$$f_{y,eq} = f_y \cdot \frac{l_{b,av}}{l_{b,req}} \quad (3.1)$$

where  $f_y$  (1.1  $f_{yk}$ ) is expected yield strength of the steel bar,  $l_{b,av}$  is the available anchorage length,  $l_{b,req}$  is the anchorage length required for full bar anchorage.

The bar length required for full anchorage was calculated based on Eurocode2 (1999) The bond stress of plain bars is given by

$$f_b = 0.36 \cdot \sqrt{f_c} \quad (3.2)$$

The required anchorage length was stated as:

$$l_{b,req} = 0.7 \cdot \frac{d_b}{4} \cdot \frac{f_y}{f_b} \quad (3.3)$$

Where  $d_b$  is diameter of the steel bar and 0.7 is a coefficient related to the existence of hook.

**Table 3.2:** Equivalent bar yield strength for insufficient anchorage.

$d_b$ , mm	$l_{b,av}$ , mm	$l_{b,req}$ , mm	$f_{y,eq}$ , N/mm <sup>2</sup>	$f_{y,eq}/f_y$
12	220	336	231	0.66
20	220	560	138	0.39

The equivalent yield strength of beam bars has insufficient anchorage (ins,  $l_b=220$  mm) as shown in Table 3.2. The insufficient anchorage lengths are observed generally bottom and montage bars of the beams. Column bar splices are 400 mm length and they would consider as fully anchored (full). Detailed information for beam cross sections are given in Table 3.3.

**Table 3.3:** Beam effective width and reinforcement details.

Concentrated plasticity model was considered for inelastic flexural behavior of elements. Torsion and shear behavior were accepted as elastic in all cases.

Instead of axial-force (M-N) and biaxial moment (M-M) interaction, a standard moment-curvature analysis was implemented for each element. For columns, to obtain moment-curvature curves, axial force corresponding to gravitational loading was considered.

XTRACT software was used to obtain moment-curvature analysis. Stress-strain models for concrete and steel materials are given in Figure 3.3.

**Figure 3.3:** Stress-strain relations for steels and concrete.

The yield curvature and ultimate curvature, and yield moments for modelling the one-component concentrated plasticity of the SPEAR building members are presented in Table 3.4 and Table 3.5, and graphically in ANNEX A. Higher moment capacity can be observed under negative bending (top bars are in tension) at beams. Curvature capacity of columns is strongly dependent on the axial force. First storey columns subjected to higher axial force have lower curvature capacity.

**Table 3.4:** Yield and ultimate curvatures, and yield moments for beams.

### 3.1.2 Validation of the mathematical model

The test building was modeled by using SAP2000 v21 software and modal results were compared with results in the paper Stratan and Fajfar (2003), taken as the basis for this structure.

Two models of the building were done in SAP2000 program. In the first one, the slabs are modeled by shell elements. The own weight of the structure is automatically calculated by the program. Additional dead loads and live loads are applied on the shell elements to compare the model with Fajfar's modal analysis results. The second model consists of only frame elements. The slab loads are applied to beams as

uniformly distributed (Figure 3.6). This model is same model with DOC3D model. The perspective views of the models are shown in the Figure 3.4.

**Figure 3.4:** The perspective views of the models.

All beams and columns were modeled as frame members. While modelling column with rectangular section, frame member was assigned at the center of the section and connected to beam members with rigid elements. (Figure 3.5)

**Figure 3.5:** Modelling of joint at the 250x750 column.

Since beams were modeled as T shape cross-sections, masses and weights were reduced by coefficients shown in Table 3.6.

**Table 3.6:** Reduction factors of mass and weight for beam cross-sections.

Element	Reduction factor of mass and weight	Element	Reduction factor of mass and weight
B1i,B5ij	0.438	B8j	0.318
B1j	0.438	B9i	0.250
B2i	0.318	B9j	0.226
B2j	0.318	B10i	0.318
B3i	0.280	B10j	0.318
B3j	0.280	B11i	0.298
B4i	0.250	B11j	0.438
B4j	0.250	B12i	0.431
B6ij	0.280	B12j	0.318
B7i	0.136	B13i	0.250
B7j	0.280	B13j	0.341
B8i	0.318	B14ij	0.250

Since the effect of the columns is more effective on the rigidity of the structure, the effect of the column reinforcement on the moment of inertia has been considered.

$$n = \frac{E_s}{E_c} = \frac{200}{27.78} = 7.19 \quad (3.4)$$

$$I = I_c + (n-1).A_s.d^2 \quad (3.5)$$

$$k = \frac{I}{I_c} \quad (3.6)$$

$$E_s = 200 \text{ GPa} ,$$

$$E_c = 27.78 \text{ GPa} ; k = 1.05$$

- For column with square cross- section

$$I_c = \frac{250.250^3}{12} = 325520833.3 \text{ mm}^4$$

$$I = \frac{250.250^3}{12} + 2(7.19 - 1)(226.19)(96)^2 = 351369464.6 \text{ mm}^4$$

$$k = \frac{I}{I_c} = 1.07$$

- For column with rectangular cross- section

In the strong direction;

$$I_c = \frac{250.750^3}{12} = 8789062500 \text{ mm}^4$$

$$I = \frac{250.750^3}{12} + 2(7.19 - 1)(339.29)(346)^2 + 2(7.19 - 1)(226.19)(115.33)^2 = 9292574314 \text{ mm}^4$$

$$k = 1.05$$

In the weak direction;

$$I_c = \frac{750.250^3}{12} = 976562500 \text{ mm}^4$$

$$I = \frac{750.250^3}{12} + 2(7.19 - 1)(452.39)(96)^2 = 1028177521 \text{ mm}^4$$

$$k = 1.05$$

Comparison of periods, storey masses and center of masses are presented in Table 3.7. One reason for the small differences between the results may be that the beam reinforcement is not considered in the moment of inertia. However, the differences are acceptable.

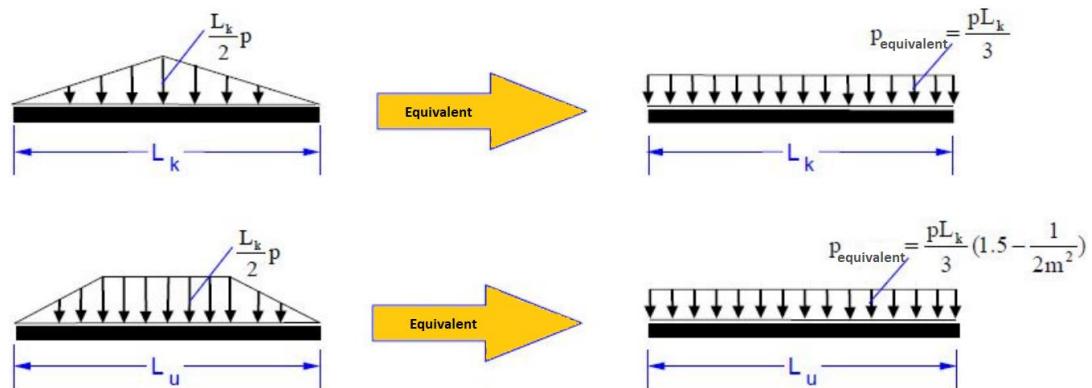

**Table 3.7:** Comparison of period, storey masses and center of masses for linear-elastic model.

		Fajfar	SAP2000
Period	T <sub>1</sub>	0.570	0.573
	T <sub>2</sub>	0.484	0.484

Mass	Floor 1&2	65.5 t	66 t
	Roof	64.1 t	64 t
Center of mass	Floor 1&2	X=4.53 m	X=4.56 m
		Y=5.29 m	Y=5.27 m
	Roof	X=4.57 m	X=4.58 m
		Y=5.33 m	Y=5.26 m

Since there exists no slab element and the loads can only be applied by uniformly distributed loads in DOC3D programme, triangular or trapezoidal distributed loads are assigned as equivalent uniformly loads by using the formulation shown in Figure 3.6.

All slabs in the structure transfers the loads in two way. Beams on long length carry trapezoidal distributed load and beams on short length carry triangular distributed load.

**Figure 3.6:** Converting triangular and trapezoidal distributed loads to equivalent uniformly distributed loads.

### 3.1.3 Earthquake records

As stated earlier, the used ground motion selection is taken from the study conducted by Stratan and Fajfar (2003) and they were selected from European Strong Motion Databank (Ambraseys et al., 2002). Seven ground motion records were used in this study. The criterias for selection of records were reported as magnitude (at least 5.8),

peak ground acceleration (at least  $1.5 \text{ m/s}^2$ ), and compatibility to the Eurocode 8 (2002) spectrum.

Acceleration elastic response spectrum defined in Eurocode 8 (2002) is used as the target spectrum (PGA= 0.2g, soil parameter  $S=1$ ,  $T_B=0.2\text{s}$ ,  $T_C=0.6\text{s}$ ,  $T_D=2.0\text{s}$ , 5% damping) and ground motion records were scaled to bring the mean of the earthquake spectra to the same level of intensity. The selected records and scaling factors are presented in Table 3.8 and characteristics of the earthquake records are given in Table 3.9.

**Table 3.8:** Earthquake records and scaling factors.

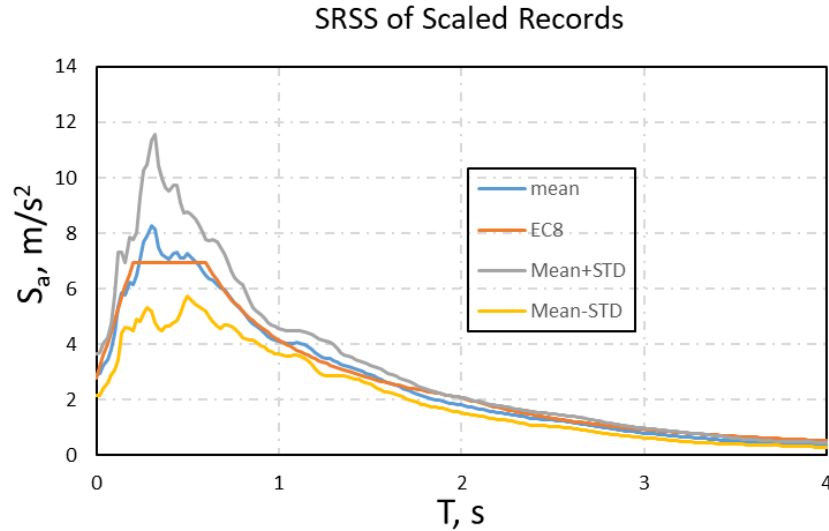

Earthquake name	Date	Station Name	Scaling factor
Alkion	24.02.1981	Korinthos – OTE Building	1.074
Alkion	24.02.1981	Xilokastro – OTE Building	0.937
Campano Lucano	23.11.1980	Calitri	0.813
Kalamata	13.09.1986	Kalamata - Prefecture	0.791
Kalamata	13.09.1986	Kalamata – OTE Building	1.047
Montenegro	15.04.1979	Ulcinj – Hotel Albatros	0.991
Montenegro	15.04.1979	Bar – Skupstina Opstine	0.388

**Table 3.9:** Characteristics of the earthquake records.

Earthquake name	Epicentral Distance	Soil Category	PGA, $\text{m/s}^2$
Alkion	20km	Soft soil	2.26 (X), 3.04 (Y)
Alkion	19km	Alluvium	2.84 (X), 1.67 (Y)
Campano Lucano	16km	Stiff soil	1.53 (X), 1.73 (Y)
Kalamata	9km	Stiff soil	2.11 (X), 2.91 (Y)
Kalamata	10km	Stiff soil	2.35 (X), 2.67(Y)
Montenegro	21km	Rock	1.78 (X), 2.20 (Y)
Montenegro	16km	Stiff soil	3.68 (X), 3.56 (Y)

Nonlinear dynamic analysis for three-dimensional structure requires bidirectional ground motion (vertical component was not considered, Stratan and Fajfar (2003)). The procedure recommended in FEMA 356, (2000) was used in this study. Due to this procedure, two horizontal components of each record are combined with using the Square Root of the Sum of Squares (SRSS) combination method, and scaling procedure is applied to SRSS target spectrum (one-directional EC8 spectrum times  $\sqrt{2}$ ). The error function, defined as the difference between the areas under the SRSS spectrum of a record and the SRSS of the target spectrum in the period range between

TC and TD, minimized by applying scaling procedure for each record separately. The target SRSS spectrum, the mean of SRSS spectra of scaled records, and the mean plus/minus standard deviation are presented in Figure 3.7.

**Figure 3.7:** Mean of the Square Root of Sum of Squares (SRSS) of scaled records and the target EC8 spectrum.

### 3.1.4 Analysis

It is clear that the stiffness values of the reinforced concrete structural elements under the effect of the earthquake are different from values predicted during the design phase. For this reason, the cracked rigidities are taken into consideration to determine the structural performance of reinforced concrete bearing systems under the influence of earthquake loads. To determine cracked rigidities, moment curvature relations are idealized as bi-linear. The slope of zero to yield point of these relations are defined as the cracked flexural rigidities. The coefficients used in SAP2000 software to reduce the moment of inertia are given in Table 3.10 for beams and Table 3.11 for columns.

**Table 3.10:** Scale factors of beams to reduce the moment of inertia.

Element	Scale factor	Element	Scale factor
B1i-B5ij	0.163	B9i	0.257
B1j	0.262	B9j	0.209
B2i	0.326	B10i	0.168
B2j	0.247	B10j	0.273
B3ij	0.177	B11i	0.269
B4i	0.366	B11j	0.152
B4j	0.204	B12i	0.152
B6ij	0.202	B12j	0.207
B7i	0.345	B13i	0.273
B7j	0.265	B13j	0.305
B8ij	0.168	B14ij	0.322

**Table 3.11:** Scale factors of columns to reduce the moment of inertia.

Element	Scale factor	Element	Scale factor
C1	0.3405	C15-X	0.2131

C13	0.3392	C26	0.1840
C14	0.2305	C27	0.2325

Modal analysis results (periods and mass participation ratios) of the structure are shown in Table 3.12. Maximum error in periods is 0.1% for mode 6. Maximum error in mass participation ratios in direction Y is about 28% for mode 7. However, the difference in mass participation ratio in direction Y is not important because the first four modes account for 90% of the total mass.

**Table 3.12:** Comparison of modal participation mass ratios and periods for inelastic model.

Mode	SAP2000			DOC3D			
	Period	U <sub>x</sub>	U <sub>y</sub>	Period	U <sub>x</sub>	U <sub>y</sub>	R <sub>z</sub>

Hinges were assigned to both ends of members as bilinear moment-curvature relationship. The definition of some hinge properties in SAP2000 program are presented in Figure 3.8 and Figure 3.9.

**Figure 3.8:** Definition of moment-curvature hinge property for columns.

**Figure 3.9:** Definition of moment-curvature hinge property for beams.

Pushover analysis was applied to structure. The first and second modes that are active in the X and Y directions respectively are considered. The pushover load cases in X and Y directions defined in SAP2000 are given in Figure 3.10 and Figure 3.11.

**Figure 3.10:** Pushover load case in X direction in SAP2000 software.

**Figure 3.11:** Pushover load case in Y direction in SAP2000 software.

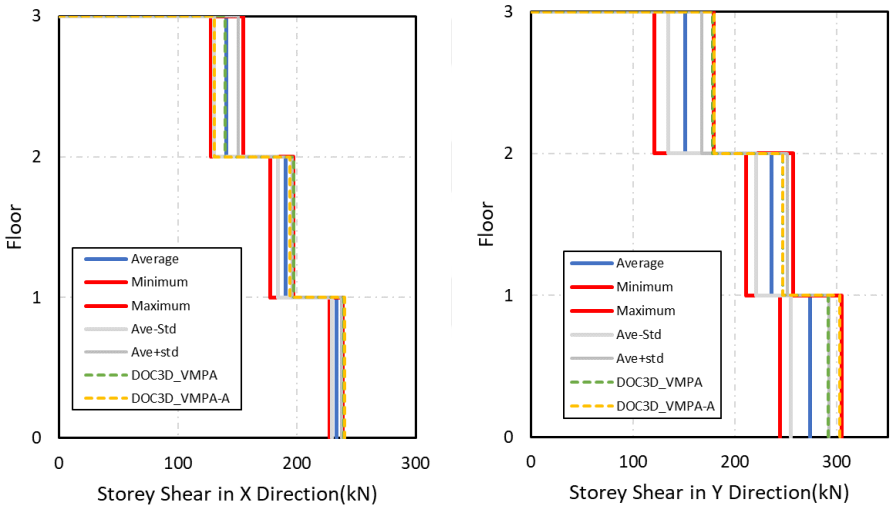

Pushover analysis are performed by using SAP2000 and DOC3D, and the capacity curves are compared with each other in Figure 3.12 and Figure 3.13. Although the capacity curves coincide in X and -X directions, there exist minor difference in Y and -Y directions. Therefore the nonlinear algorithm in DOC3D is validated.

**Figure 3.12:** Pushover curves in the X and Y directions.

VMPA procedure is applied by using DOC3D. The results of the procedure were compared with results obtained from the NTHA to assess the success of the VMPA procedure. Two different approaches namely, equal displacement rule and application of NTHA to modal SDOF capacity curves are applied to estimate the displacement demands for each mode. The evaluated demand parameters are shear forces, storey displacements, drifts, and the distribution of column and beam curvatures.

Storey shear forces are shown in Figure 3.13. Four different combinations were considered to find maximum shear force. These combinations were created considering the positive or negative effects of  $U_x$ ,  $U_y$  and  $R_z$  directions. (+ + +, - + +, + - +, - - +)

**Figure 3.13:** Storey shear forces in the X and Y directions.

In the graphics that show storey shear forces, blue line shows average value of NTHA results, red lines show maximum and minimum values, grey lines represent average+STD and average-STD values, green dash line shows the results obtained from VMPA with equal displacement rule, yellow dash line represents the results obtained from VMPA-A with equal displacement rule. When VMPA and VMPA-A results are compared, storey shear forces are almost the same in some floors in both direction. However, VMPA procedure results are better than VMPA-A results. If VMPA is interpreted, it is seen that shear force values in X direction have a maximum 3.9% error on the second floor. On the other hand, in the Y direction, where torsional effect is more, maximum error is 17.7% on the third floor.

Curvature values of columns are shown in Figure 3.14, Figure 3.15 and Figure 3.16. Column C2, C7 and C6 are chosen to compare curvature distribution of columns. Blue line, yellow lines and red lines represent average, average+STD and average-STD, and maximum and minimum values obtained from NTHA, respectively. Green and black dash lines represent VMPA and VMPA-A results, respectively. Graphics at the left handside show the results obtained from equal displacement rules and right handside show the results obtained from application of NTHA to modal SDOF capacity curves approach. In the X direction, for C2 column , VMPA-A results are more consistent than VMPA results. However, in the Y direction, VMPA results are better than VMPA-A. For C7 and C6 column, VMPA procedure is more accurate than VMPA-A.

**Figure 3.14:** Curvature values of column C2 in the X and Y direction.

**Figure 3.15:** Curvature values of column C7 in the X and Y direction.

**Figure 3.16:** Curvature values of column C6 in the X and Y direction.

Curvature values of beams are shown in Figure 3.17, Figure 3.18, Figure 3.19 and Figure 3.20. Blue line, yellow lines and red lines represent average, average+STD and average-STD, and maximum and minimum values obtained from NTHA, respectively. Green and black dash lines represent VMPA and VMPA-A results, respectively. Graphics at the left handside show the results obtained from equal displacement rules and right handside show the results obtained from application of NTHA to modal SDOF capacity curves approach. Eight beams which are close to each corner of the structure in plan, are chosen to compare curvature values with NTHA. B5i, B6j, B1i and B2j are the beams in the X direction, and B12i, B11j, B8i and B7j are the beams in the Y direction. Based on the load direction the moment values at the supports can exceed the negative moments obtained from gravity loads. Since, the positive moment capacity of the beams are very smaller than the negative ones, positive curvatures are considered to evaluate nonlinear behavior. In the X direction, the difference between VMPA and VMPA-A results are small, especially for beam B5i which is close to stiff

edge. For beams B5i and B2j which are close to stiff and flexible edge respectively, the results are not accurate for both procedures.

**Figure 3.17:** Curvature values of beams B5i and B6j in the X direction.

**Figure 3.18:** Curvature values of beams B1i and B2j in the X direction.

In the Y direction, the results of both procedure are acceptable. In stiff edge (B12i), the results of VMPA-A procedure is almost the same with NTHA results. However, for other beams, VMPA results are more accurate than VMPA-A results.

**Figure 3.19:** Curvature values of beams B12i and B11j in the Y direction.

**Figure 3.20:** Curvature values of beams B8i and B7j in the Y direction.

Since, the VMPA procedure has better results for the SPEAR building, in the evaluation of other seismic demands, only VMPA results are considered.

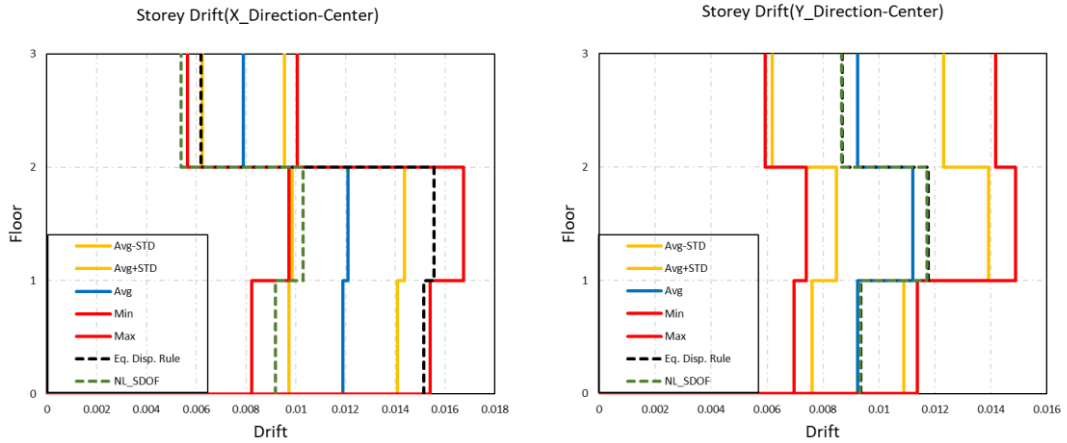

Storey displacements can be shown in Figure 3.21. In X direction, there is a huge difference between two approaches. The application of NTHA to modal SDOF capacity curves concept approach is more conservative than equal displacement rule. These two approaches coincide in Y direction. In Y direction, the application of NTHA to modal SDOF capacity curves concept is more consistent at the center point, on the other hand, in X direction, storey displacements at the flexible edge have better results than other points.

**Figure 3.21:** Storey displacement demands at the center of mass, stiff and flexible edges in the X and Y direction.

Storey drifts are presented in Figure 3.22. Storey drifts at center point in the Y direction have about 6% error for both approaches. However, in the X direction, the approaches have different results and NTHA to modal SDOF capacity curves approach is more consistent than equal displacement rule.

**Figure 3.22:** Storey drifts at the center of mass in X and Y direction.

### 3.1.5 Results

VMPA and VMPA-A are used here for a typical existing three-storey building, which has an asymmetric-plan, to verify the methods against NTHA results by comparing some demand parameters. The following conclusions are drawn from the study:

- 1) When storey forces are considered, VMPA procedure is more accurate than VMPA-A procedure, especially in the direction that torsional effect is higher. The error rate of the floor forces is acceptable for VMPA. Due to the torsion effect in the Y direction is greater, the error rate is higher.
- 2) When the curvature values of column C2 which is corresponding to stiff edge, are examined, in the X direction, the results obtained by equal displacement rule and application of NTHA to modal SDOF capacity curves method are the same, and VMPA-A procedure is more consistent than VMPA procedure. On the other hand, in the Y direction, VMPA procedure is more consistent than VMPA-A procedure especially for the results obtained from equal displacement rule. For column C7, in the X direction, VMPA procedure has better results than VMPA-A, except first floor, and in the Y direction, at all floors, VMPA with equal displacement rule method has more convenient results. For column C6 which has rectangular cross section, VMPA-A procedure has larger error at first floor for both direction and approaches.
- 3) In the X direction, the difference between beam curvature results of VMPA and VMPA-A procedures are small, especially at beam B5i which is close to

stiff edge. For beams B5i and B2j which are close to stiff and flexible edge respectively, the results are not accurate for both procedures. In the Y direction, the results of both procedure are acceptable. In stiff edge (B12i), the results of VMPA-A procedure is almost the same with NTHA results. However, for other beams, VMPA results are more accurate than VMPA-A results.

- 4) Storey displacements in the Y direction of both approaches give similar results. When the results are examined, it is seen that the difference between NTHA results and VMPA is increased as moving from center point to stiff and flexible edge. On the other hand, in the X direction results of the both approach have different story displacement values and application of NTHA to modal SDOF capacity curves method has a better result due to the implementation of the method.
- 5) When storey drifts at the center of the mass are compared, in the Y direction, both approaches have similar results and maximum error is at the third floor with 6%. In the X direction, the difference between the results of two approaches are larger, at first and second floor application of NTHA to modal SDOF capacity curves method has better results and maximum error occur at second floor with about 15%, however, at the third floor equal displacement rule approach results are better than the other, and error value is about 21%.

### **3.2 20-Storey SAC Building**

Twenty storey SAC building, which was designed for Los Angeles (LA) region (Gupta and Krawinkler (1999)), is a steel structure and selected as a benchmark structure for this study. The structure is 30.48 m by 36.58 m in plan, 80.77 m in elevation. There are 5 bays in the N-S direction and 6 bays in the E-W direction. The bays are 6.10 m in both directions. The outer bays of the structure contain Moment Resisting Frames (MRFs) and the interior bays includes gravity frames. Loads on the slabs are assumed to be transferred by secondary beams on the beams in N-S direction. Plan and elevation view of the 20-storey SAC buildings shown in Figure 3.23.

The yield strength of columns and beams are taken as 345 MPa and 248 MPa, respectively.

**Figure 3.23:** Elevation and plan view of the 20-storey SAC buildings.

### 3.2.1 Modelling of elements

The corner columns have tube cross section and others have I-shape cross section. The column sizes change at splices which are 1.83 m above some floor levels. Cross section of beams and columns are given in Table 3.13 and Table 3.14 for each floor.

**Table 3.13:** Cross sections of columns and beams for MRFs.

Loads on slabs were transferred to beams in the N-S direction with secondary beams. Loads were determined by using a trial and error method.  $G+0.3Q$  load combination values for each storey are given in Table 3.15. Mass of structural members were considered as zero. After analysing the structure, storey masses were compared with storey masses given in Ohtori et al. (2004). The difference between the storey masses are approximately 10 tonnes (Table 3.15), and this difference can be acceptable.

**Table 3.15:** Comparison of storey masses.

Floor	Storey masses	
	Ohtori et al.	SAP2000
20 <sup>th</sup> floor	584 t	574.78 t
2 <sup>nd</sup> -19 <sup>th</sup> floor	552 t	543.42 t
1 <sup>st</sup> floor	563 t	553.84 t
Ground floor	532 t	522.48 t

Storey masses are considered as a point mass for modal analysis (5% eccentricity is applied). Rotational mass values were calculated by using following equation;

$$\left( \frac{a^2 + b^2}{12} \right) . m \quad (3.7)$$

Where a and b are the lengths of the structure in the X and Y direction, and m is the storey mass value.

Translational mass and rotational mass of the storeys are given in Table 3.16.

**Table 3.16:** Translational and rotational masses of each storey.

Floor	Translational mass	Rotational mass
20 <sup>th</sup> floor	574.78 t	108720.12 tm <sup>2</sup>
2 <sup>nd</sup> -19 <sup>th</sup> floor	543.42 t	102788.35 tm <sup>2</sup>
1 <sup>st</sup> floor	553.84 t	104759.30 tm <sup>2</sup>
Ground floor	522.48 t	98827.53 tm <sup>2</sup>

Modal participation mass ratios and periods were obtained after modal analysis of elastic model. Comparison of modal participation mass ratios and periods are given in Table 3.17. The difference between the results of SAP2000 and DOC3D model are acceptable. Since the outputs of two program have approximate results, it was accepted that the modeling was done correctly and nonlinear analysis procedure can be started.

**Table 3.17:** Comparison of participation mass ratios and periods for elastic model.

Concentrated plasticity model was considered for inelastic flexural behavior of elements. A standard moment curvature analysis was implemented for each member instead of biaxial moment (M-M) and moment-axial force (M-N) interaction. For columns, axial force corresponding to gravitational loading was considered to obtain moment curvature relationship. XTRACT software was used to obtain moment curvature analysis. For beams, following equations were used to obtain moment curvature relationships.

$$M_p = \sigma_y \cdot W_p \quad (3.8)$$

Where,  $\sigma_y$  is the yield strength of steel material,  $W_p$  is the plastic section modulus and  $M_p$  is the moment capacity of the cross-section.

$$\phi_p = \frac{M_p}{EI} \quad (3.9)$$

Where,  $\phi_p$  is the curvature corresponding to  $M_p$ .

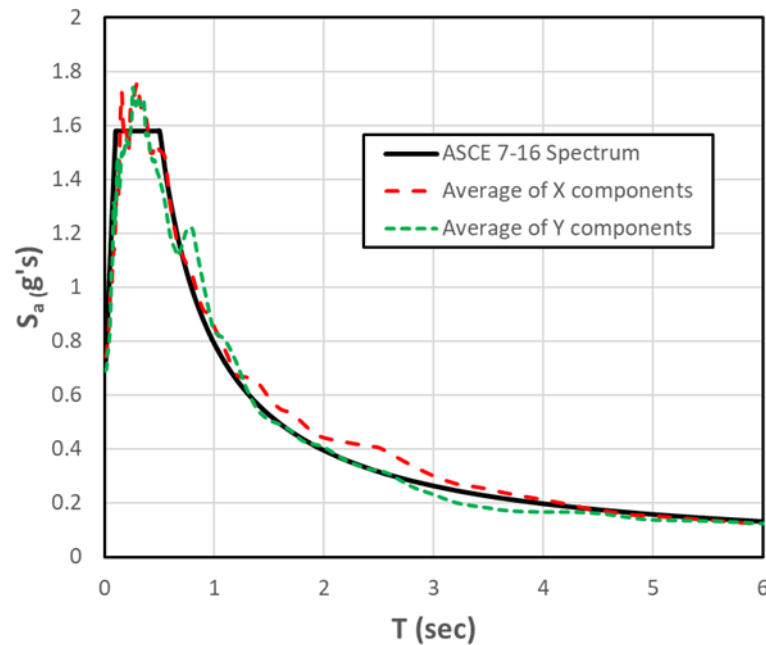

Moment capacity and yield curvature of beams are shown in Table 3.18, and moment capacity and yield curvature of columns in both direction X and Y are given in ANNEX B and moment curvature relationship of beams and columns are given in ANNEX C.

**Table 3.18:** Moment capacity and yield curvature of beams.

Element	Moment Capacity	Yield Curvature
W14x22	135	0.00814

### 3.2.2 Earthquake records

Fourteen ground motion records were selected from the PEER ground motion database (2006). The selection criteria is to match the average spectrum of X and Y components of ground motions with target ASCE/SEI 7-16 (2017) spectrum. For Los Angeles region, the spectral characteristics are given as  $S_{ds}=1.58$ ,  $S_{d1}=0.79$  and  $T_L=8$  sec in ASCE/SEI 7-16 (2017). The average Spectrum in X and Y directions and target spectrum is given in Figure 3.24.

**Figure 3.24:** The average spectrum of selected records and target spectrum.

The selected records and scaling factors are presented in Table 3.19.

**Table 3.19:** Earthquake records and scaling factors.

### 3.2.3 Analysis

Hinges were assigned to both ends of members as bilinear moment curvature relationship. Definition of column and beam hinge properties are shown in Figure 3.25 and Figure 3.26.

**Figure 3.25:** Definition of moment-curvature hinge property for column.

**Figure 3.26:** Definition of moment-curvature hinge property for column.

Pushover analysis was applied to structure in the X and Y direction that the first two modes of the structure are effective. The application of pushover analysis in the X and Y direction are shown in Figure 3.27 and Figure 3.28.

**Figure 3.27:** Definiton of NSP in X direction in SAP2000 software.

**Figure 3.28:** Definiton of NSP in X direction in SAP2000 software.

Pushover curves of the structure are presented in Figure 3.29. It can be seen that SAP2000 and DOC3D results are the same in both direction.

**Figure 3.29:** Pushover curves in the X and Y directions.

To determine seismic demands of the structure, VMPA and VMPA-A procedures were applied by using DOC3D matlab programme, the results are compared with NTHA by using SAP2000 software.

In the storey shear and curvature graphs, first two storeys represent basement floors and in the storey displacement and storey drift graphs, basement floors were not considered, storey numbers are started from first floor.

Storey shear forces are given in Figure 3.30. It shows that the results obtained from VMPA-A procedure is more accurate than others, and the results obtained from VMPA with equal displacement rule approach has larger error than other approach.

**Figure 3.30:** Storey shear forces in the X and Y direction.

The curvatures of bottom sections of columns are presented in Figure 3.31 and Figure 3.32. For corner column (A1), VMPA-A procedure is more consistent than others in the X direction. However, when Y direction is considered, the consistency of approaches changes floor by floor.

**Figure 3.31:** Curvature values of the corner column (A1).

When the curvature values of the mid-columns (C1 for direction X and A4 for direction Y) of the MRFs are considered, it can be seen that all approaches have approximately

the same results. On the other hand, in the X direction, VMPA-A procedure is more accurate, but after third floor, curvature values are not consistent with exact solution.

**Figure 3.32:** Curvature values of the mid-column of the MRFs in both X and Y direction, C1 and A4 respectively.

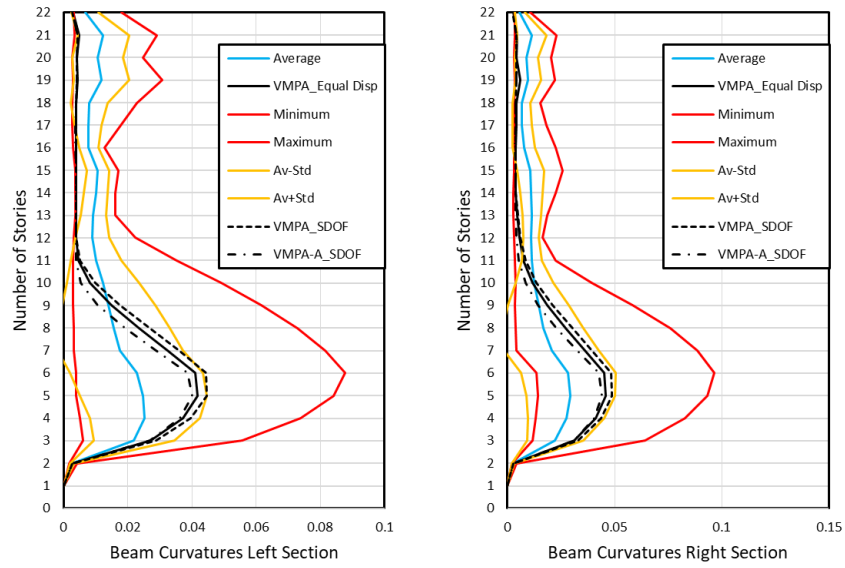

Curvature values for beams in the X direction are given in Figure 3.33 and Figure 3.34, and curvature values for beams in the Y direction are given in Figure 3.35 and Figure 3.36. In the figures, right section shows the maximum values and left section shows the minimum curvature values. VMPA-A procedure is more accurate than other procedures for all selected beams. In the X direction, there are difference between results, and VMPA procedure with equal displacement rule results are not in acceptable range. In the Y direction, all results are in acceptable range and the difference between them are small. However, VMPA-A solution is more convenient than others.

**Figure 3.33:** Curvature values of the beams located at  $x=0$  and  $x=6.1$  m when  $y=0$ .

**Figure 3.34:** Curvature values of the beams located at  $x=12.2$  and  $x=18.3$  m when  $y=0$ .

**Figure 3.45:** Curvature values of the beams which located at  $y=12.2$  and  $y=18.3$  m when  $x=0$ .

**Figure 3.56:** Curvature values of the beams which located at  $y=30.5$  and  $y=36.6$  m when  $x=0$ .

Storey displacement values are shown in Figure 3.37. According to figure, the results obtained from VMPA-A procedure are close to the results obtained from NTHA.

**Figure 3.37:** Storey displacements of the SAC20 buildings in X and Y directions.

Storey drift values are presented in Figure 3.34. In the X direction, VMPA-A procedure has better results up to seventh floor. After ninth floor, VMPA procedure with equal displacement rule approaches has more accurate results than others. In the Y direction, at lower floors VMPA-A procedure is accurate. Towards the upper floors VMPA with equal displacement rule approach has better results.

**Figure 3.38:** Storey drifts of the structure in X and Y directions.

### 3.2.4 Results

VMPA and VMPA-A are used here for a high-rise building to verify the methods against NTHA results by comparing some demand parameters. The following conclusions are drawn from the study:

- 1) For SAC building, in the X direction shear force results obtained from VMPA procedure with equal displacement rule are in acceptable range except basement floors. In the Y direction, relative difference of the results obtained from VMPA procedure with equal displacement rule are changing floor by floor.
- 2) For SAC building, curvature values of column in both direction are not consistent. Relative difference of the procedures are inconsistent, VMPA procedure is inadequate to calculate column curvatures for high-rise buildings. Curvature results of beams in the X direction which is the same direction with dominant period, for left section, results obtained from VMPA procedure with equal displacement rule are not in acceptable range. Curvature results of beams in the Y direction are in acceptable range for all approaches.
- 3) For SAC building, storey displacements are in acceptable range in both directions. However, in the X direction, application of NTHA to modal SDOF

capacity curves approach has more convenient results than equal displacement rule.

- 4) VMPA-A procedure with application of NTHA to modal SDOF capacity curves approach has more accurate results for all demand parameters in both direction X and Y. However, VMPA procedure with equal displacement rule can be recommended due to convenience in application and time.
- 5) The results obtained from VMPA procedure with equal displacement rule are more inconvenient than others in the X direction. However, in the Y direction VMPA procedure with application of NTHA to modal SDOF capacity curves approach has more inconvenient than other although the results of all procedures are considered.

#### 4. CONCLUSIONS

In this study, a variant modal pushover analysis (VMPA) and adaptive version of VMPA (VMPA-A) are utilized to evaluate seismic performans of an asymmetric plan building and a high-rise building.

Two example buildings namely, SPEAR building and 20-story SAC Steel building have been analyzed to assess the success of the mentioned procedures by comparing the analysis result with those of NTHAs. The following conclusions can be drawn from these study:

- 1- Pushover curves obtained from DOC3D is validated by using SAP2000 software for the two structures.
- 2- For asymmetric plan building, shear force results obtained from VMPA and VMPA-A procedures are in acceptable range, and the results obtained from VMPA procedure with equal displacement rule has better results.
- 3- For SPEAR building, column curvature results are inconsistent escipacially in the Y direction. The procedures are inadequate to calculate column curvatures. Curvature results of the beams in the X direction which is the same direction with dominant period, are inconvenient. The result in the Y direction are in acceptable range.
- 4- For SPEAR building, in the X direction, storey displacement values obtained from VMPA procedure with equal displacement rule are in acceptable range only in the stiff edge. When the flexibility increase, inconsistency in the results increase. On the other hand, VMPA procedure with application of NTHA to modal SDOF capacity curves approach has acceptable results for stiff, center and flexible point. In the Y direction, the result at all point are in acceptable range.
- 5- For 20-storey SAC Steel building, in the X direction shear force results obtained from VMPA procedure with equal displacement rule are in acceptable

range except basement floors. In the Y direction, relative difference of the results obtained from VMPA procedure with equal displacement rule change floor by floor.

- 6- For 20-storey SAC Steel building, curvature values of column in both direction are not consistent. Relative difference of the procedures are inconsistent, VMPA procedure is inadequate to calculate column curvatures for high-rise buildings. Curvature results of beams in the X direction which is the same direction with dominant period, for left section, results obtained from VMPA procedure with equal displacement rule are not in acceptable range. Curvature results of beams in the Y direction are in acceptable range for all approaches.
- 7- For 20-storey SAC Steel building, storey displacements are in acceptable range in both directions.
- 8- For SPEAR building, VMPA procedure with application of NTHA to modal SDOF capacity curves approach is more convenient than others. However, equal displacement rule approach can be preferred since the results are conservative and application of equal displacement method is practical.
- 9- For 20-storey SAC Steel building, generally, VMPA-A procedure with procedure with application of NTHA to modal SDOF capacity curves approach has better results especially at lower floors. At the upper floors, all approaches have the results that are closed to each other.
- 10- In both structure, in the Y direction, the results obtained by equal displacement rule and application of NTHA to modal SDOF capacity curves approaches are almost the same results since the equal displacement rule approach already provides the seismic demands.
