We hereby recommend that the thesis entitled "A Decision Support System for Quality Control" submitted by Fikret Omit Aktan be accepted in partial fulfillment of the requirements for the degree of Master of Science in Industrial Engineering in the Institute for Graduate Studies in Science and Engineering, Boğaziçi University.

EXAMINING COMMITTEE

Doç.Dr.Gündüz ULUSOY
(Thesis Advisor)

Yrd.Doç.Dr.A.Rıza KAYLAN

Doç.Dr.Seyhan TUĞCU

DATE:

ACKNOWLEDGEMENTS

I wish to express my sincere gratitude to my thesis advisor, Doç.Dr.Gündüz Ulusoy, for his invaluable guidance and his continuous support, encouragement and understanding throughout all phases of this study.

I also sincerely wish to thank Dr.Ali Rıza Kaylan for his valuable comments and suggestions.

I also would like to thank my sister, Ufuk Aktan, for her help in preparing the drawings.

ABSTRACT

The important role of Quality Control in the economic growth of Turkey has become a well-known fact, especially in the last few years when Turkey has increased her efforts for expanding the exports.

However, Quality Control is not understood and utilized effectively as a management tool in most of the Turkish industrial companies. There exists a large gap between the practical applications and the theoretical developments in statistical quality control techniques, due to a lack of understanding of QC by managers.

In this study, Decision Support Systems (DSS) are proposed as a tool that would be helpful in filling this gap, by leading the managers towards the use of scientific management approach in making decisions related to quality improvement.

Quality Control activities are conducted through various decisions ranging from short-term to long-term taken at different levels of management. In this study, only one of these decisions is taken into consideration and it is aimed to give support to one of the basic activities of QC, namely the feedback mechanism between production and management.

Thus, a decision support system is designed to aid the management in fighting with the chronic quality problems, in a way to provide a set of capabilities expected from a DSS, in general.

This decision support system which will be called QCDSS, is an interactive computer-based system which helps the decision-maker in the identification of vital chronic quality problems, and in the evaluation of possible precautions that can be taken to give remedy.

QCDSS combines flexible, ad hoc data analysis capabilities with some models. This integration is achieved through a user-friendly dialog component. The problem identification phase of the decision is supported by a systematic Pareto analysis model which will be called "Failure Analysis Module" while a Monte-Carlo simulation model embedded in the "Revision of the Inspection Plan Module" is utilized to support the alternative evaluation phase.

QCDSS is developed for a light bulb manufacturing company where production is continuous and controls are by attributes.

ÖZET

Özellikle son yıllarda ihracatı artırma gayretlerinin yoğunlaşmasıyla birlikte, Kalite Kontrolün Türk ekonomisinin gelişmesindeki önemi herkesçe bilinen bir gerçek haline gelmiştir.

Ancak, Kalite Kontrol Türk Sanayiinin büyük bir bölümünde bir yönetim aracı olarak anlaşılmamakta ve etkin bir şekilde kullanılmamaktadır. İstatistiksel kalite kontrol teknikleri üzerindeki teorik çalışmalarla bunların sanayideki uygulamaları arasında, Kalite Kontrolün yöneticileri tarafından yeterince kavranılmamış olmasından ileri gelen bir uçurum vardır.

Bu çalışmada, Karar Destek Sistemleri (KDS) yöneticilerinin kalitenin iyileştirilmesiyle ilgili kararları almada bilimsel yönetim yaklaşımını kullanmalarını sağlayacak ve dolayısıyla bu uçurumu doldurmaya yarayabilecek bir araç olarak önerilmektedir.

Kalite Kontrol etkinlikleri yönetim şemasının çeşitli kademelerinde alınan kısdan uzun vadeye birçok kararlar yoluyla yönetilmektedir. Bu çalışmada, bu kararlardan yalnızca biri ele alınmış, Kalite Kontrolün ana etkinliklerinden biri olan üretim ve yönetim arasındaki geribesleme mekanizmasının desteklenmesi amaçlanmıştır.

Bu amaçla, kronik kalite problemlerinin çözümüne yönelik bir karar destek sistemi, genel anlamda bir KDS'den beklenebilecek bir dizi özellik dikkate alınarak geliştirilmiştir.

QCDSS adı verilen bu karar destek sistemi, önemli kronik kalite sorunlarının belirlenmesi ve bunların giderilmesi için alınabilecek önlemlerin değerlendirilmesi aşamalarında karar vericiye yardım eden etkileşimli bir bilgisayar sistemidir.

QCDSS karar vericinin istemine ve problemin özelliklerine uyarlanabilir veri analizi olanaklarıyla bazı modelleri, kolay kullanımlı diyalog ögesinin yardımıyla kaynaştırmaktadır. Kararın problemin belirlenmesi aşaması "Hata Analizi" adı verilen sistematik bir Pareto analizi modeli tarafından desteklenirken, seçeneklerin değerlendirilmesi aşamasını "Kontrol Planının Yenilenmesi Modülü"nde yer alan bir Monte-Carlo benzetim modeli desteklemektedir.

QCDSS, sürekli üretim ve nitelik kontrollerinin geçerli olduğu, ampul üretimi yapan bir fabrikada uygulanabilecek biçimde geliştirilmiştir.

I. INTRODUCTION

In this chapter, it is aimed to underline the fact that quality control activities have an important role in the Turkish economy, and they need to be improved through scientific management approach. DSS is suggested as a tool for improving the quality level of the Turkish industrial products.

For this purpose, after a brief discussion of the Quality Control application in Turkey, the concept of DSS will be introduced and benefits possible from a DSS in QC will be considered.

I.1. QUALITY CONTROL APPLICATION IN TURKEY

1.1.1. Importance of Quality Control in Turkey

One of the most important bottlenecks in the Turkish economy is the deficit in foreign payment balance which follows an increasing trend.

Taking the import-export structure of our country into consideration (See Table 1.1) it is seen that the growth of the Turkish economy highly depends on the ability of increasing foreign payment opportunities. The most healthy

TABLE 1.1- Foreign Trade Structure of Turkey

and confident way to accomplish this is increasing the export income parallel to the increase in the import expenditure. Various short and long term precautions should be taken to expand the export, and thus, decrease the pressure on foreign payment balance.

One of the main precautions to be taken in the long run is changing the structure of exports in Turkey, which is highly dependent on certain agricultural products. This change in export structure can be accomplished by continuously increasing the share of industrial products in total export income.

This improvement can be achieved in the long run by an export-oriented, rational, coordinated industrialization policy.

Main concerns of such a policy should be optimum resource allocation, standardization and product quality.

As a matter of fact, in many studies on the subject it is stated that one of the main reasons for the low progress rate in export is the low quality level of the exported goods and the lack of standardization(1,2,3,4).

Developing countries generally encounter harsh competition conditions in international markets. Therefore, quality level and cost play a crucial role in the export of industrial products.

To achieve competitive levels on quality and unit cost, industrial organizations should apply scientific management rules. Production planning, process cost analysis and statistical quality control during all phases of production should be effectively used as management tools.

1.1.2. Practice and Management of QC in Turkish Firms

Although Quality Control has such an important role in economic growth of Turkey, the practice of QC in industry is quite limited and insufficient.

Apart from a few companies which have organized QC systems, what is done usually is a simple grading of the final product for the purpose of determining the sales price.

This lack of efficient QC systems arise from the absence of a number of important features of modern QC application. In general, the following shortcomings account for the insufficient practice:

- (i) Having no predefined quality objectives;
- (ii) Insufficient data on
 - technology
 - labor
 - material
 - cost
 - field-service, etc.;
- (iii) Not having any preset acceptance criteria;
- (iv) Lack of a proper reporting system;
- (v) Low use of statistical QC;
- (vi) Absence of research and development activities,
- (vii) Poor calibration or lack of equipment;
- (viii) Unsatisfactory management-labor relationships;
- (ix) Absence of training programs;
- (x) Insufficient coordination and information flow among various departments;
- (xi) Lack of part standardization.

It is not a surprise that efficient decisions on quality related problems cannot be made in environments where

a few of the above shortcomings co-exist.

The value of QC as a management tool and the impact of quality-cost reduction on profits is not well understood(5).

Quality costs (internal and external failure costs, appraisal costs and prevention costs) are not quantified and the net gain that would be brought by quality planning is not known.

The belief that QC only judges the level of quality in a certain product and it does not add value to that product cause the production and management underutilize and underrate QC efforts.

The "total quality control" concept is rarely applied. Thus, the chance of "catching the defective at its source" is missed and high losses in material and labor are suffered.

Furthermore, the real purpose of inspection is sometimes missed, resulting in the substitution of a "inspect it better" attitude in place of "make it better"(6).

In many cases, it is seen that, even though quality data of considerable volume and sophistication is produced through the use of some highly technical and expensive equipment, this information is rarely used to control the quality of the production. Often, the reason is that the information feedback to the production line is too slow to be of use-the product leaves the factory before the analyses reach the production engineers.

Many of these problems encountered in the use of QC as a management tool, are not typical for our country, only. A recent survey in the United Kingdom chemical manufacturing

industry revealed surprisingly low use of statistical quality control techniques because of lack of understanding(7). The main reasons for the non-adoption of statistical methods identified in this study will be given here since the situation is very similar to that in Turkey.

In most of the companies who did not use statistical quality control (SQC),

- (i) they were unaware of SQC techniques,
- (ii) they were aware of SQC techniques, but never tried them,
- (iii) there was a lack of understanding of SQC techniques.

Most of the QC managers revealed their beliefs that "SQC would involve a great deal of work", "it was much quicker and reliable to use the judgement of experienced individuals", "the theory would not work in real life", "the production managers were reluctant to get involved in statistics and numerical analysis".

It is more than 50 years since Shewhart' (1931) introduced the concept of SQC. Since then, many extensions and modifications have been made, offering a wide range of effective techniques. There exists, however, a large gap between the practical applications of and the academic researches in the statistical techniques of quality control. Considerable advances in the basic knowledge and understanding of QC by managers are required before advantage can be taken of these developments.

1.2. DECISION SUPPORT SYSTEMS

Together with the rapid development in computer technology, such as personal computers, computer networks, large data bases, color graphics and computer-based models, there is an increasing interest in the use of computers to support decision making. Such uses are being called Decision Support Systems (DSS).

In this section, it will be discussed what is really meant by the term "Decision Support Systems". The aim and main characteristics of DSS, the differences between DSS and traditional TPS (Transaction Processing Systems) and MIS (Management Information Systems), the framework of a DSS and the design approach are further issues to be discussed through a literature survey.

1.2.1. A Formal Definition of DSS-Is It Possible?

The concepts involved in DSS were first presented by Micheal S.Scott Morton under the term "Management Decision Systems", in the early 1970's.

He explored the possibilities for improvement in management problem solving through the use of a visual display device. His understanding of such a system can be found in the following paragraphs (p.6 of (8)):

"Observation of managers at work indicates that they spend a large portion of their time in verbal communication with others. This is also true within a decision-making cycle; that is, the process of defining and solving problems is often accomplished by "talking" the problem through to solution.

The internal and very informal "model", or set of guidelines, that each manager has in his mind is used by him as a frame of reference against which to pass the facts that he perceives in a conversation. From this, and other sources he develops his definition of a problem—that is, a difference between what his internal "model" says is expected and what he actually perceives. Similarly, he has informal models or processes that he uses to solve problems as he perceives them. In both cases the problem finding and problem solving are intuitive judgemental kinds of processes.

It seems desirable to leave the manager with this freedom but also help him build as firm a base from the facts as possible—and only then have him apply his judgement to this base. This is done by providing him with flexible access to the data and by making available the use of relevant formal models to process and filter the data for him. There is a rapidly expanding technology in the field of Operations Research and mathematical models. This technology can be brought to bear on problems and made to support the manager's decision. The computer technology and the modelling technology will allow this, and it is clear that this technology can be used by normal line managers with considerable benefit".

Connecting the keywords in these paragraphs and in later works which extend these ideas, DSS can be defined as, interactive computer-based systems that help decision makers utilize data and models to solve unstructured problems.

However, as expressed by Carlson and Sprague(9), this definition is quite restrictive and a few actual systems can satisfy it completely.

Furthermore the term "unstructured" in this definition, caused a confusion which raised a debate in DSS literature.

Using Simon's(10) definition, decisions can be classified as structured (programmable) or unstructured (non-programmable) depending on whether or not the decision-making process can be described in detail before making the decision. A decision may be unstructured because of novelty, time-constraints, lack of knowledge, large search-space, multi-dimensionality, complex interrelationships, requirement for managerial judgement and nonquantifiable data, dynamic environment, or other reasons.

However, a problem can only be structured "with regard to" a particular decision maker, or a well-defined set of decision makers(11). In other words, the concept of "structure" in decision making is heavily dependent on the cognitive style and approach to problem solving of the decision maker. Thus, it is both misleading and incorrect to speak of "structured" or "programmed" problems in the general case.

As a second attempt for a definition, the term itself, whose origin is straight forward enough, can be used in the way Moore and Chang suggest (p.8 in(11)):

"1- Decision-emphasises the primary focus on decision making in problem situations rather than simply information retrieval, processing or reporting;

2- Support-clarifies the computer's role in aiding rather than replacing the decision-maker, thus including those decision situations with sufficient "structure" to permit computer support, but in which managerial judgement is still an essential element;

3- System-highlights the integrated nature of the overall approach, suggesting a wider context of man, machine and decision environment".

This time, however, the definition is too broad.

So, here, instead of a formal definition, the "characteristic" approach used by Carlson and Sprague(9) will be used, to give an understanding of DSS.

The following characteristics are the capabilities which are required to accomplish the objectives that DSS are designed to accomplish:

(i) They tend to be aimed at less well-structured, underspecified problems that upper-level managers typically face. Here, the concept of "structuredness with regard to" a particular decision-maker will be used.

(ii) They attempt to combine the use of models or analytic techniques with traditional data access and retrieval functions.

(iii) They specifically focus on features that make them easy to use by noncomputer people in an interactive mode.

(iv) They emphasize flexibility and adaptability to accommodate changes in the environment and in the decision making approach of the user.

In this study, these guidelines will be used to distinguish DSS.

1.2.2. Information Systems and DSS

The next issue discussed in literature is the role of DSS in the overall context of information systems.

In fact the definitions given in the previous section make it clear that DSS is not an outgrowth of TPS or MIS.

However, because of the confusion caused by some highly data-oriented applications of DSS, DSS school of thought had some trouble in distinguishing its work from previous efforts in MIS development.

As a result, an attempt to draw a sharp distinction between MIS and DSS came up in the DSS literature.

Although such a rigid classification does not seem tenable, there are some subtle but significant distinctions between DSS and traditional TPS and MIS approaches.

The characterization given by Moore and Chang will be used in this study to distinguish between them (p.9 of (11)):

"1- Transaction Processing System (TPS)-Pure data processing programs for gathering, updating and posting information according to pre-defined procedures. Examples include a basic payroll system or an order processing system;

2- Management Information System (MIS)-A system with pre-defined aggregation and reporting capabilities, often built upon TPS. Examples are a payroll system with managerial reports, such as a labor distribution summary;

3- Decision Support System (DSS)-An extensible system with intrinsic capability to support ad hoc data analysis and reduction as well as decision modelling activities.

From a descriptive standpoint, TPS are frequently devoted to routine data processing tasks, involving high degree of formality, timeliness, accuracy and efficiency in

the processing of comparatively large volumes of data. MIS are often "report-oriented" in the sense that data is extracted and summarized into pre-defined formats, often on a periodic basis, for purposes of managerial review in reporting exceptions, deviations from standards, and historical trends. DSS subsume portions of an MIS system; especially the summarization and extraction capabilities, but the procedures for effecting this are more loosely defined, thereby permitting the user to select on an ad hoc basis the frequency and to a limited extent, the content of reports. The key notion is that the usage of DSS by the user is, within limits, not pre-specified and is aperiodic in contrast to MIS usage".

This "key notion" is believed to be essential in distinguishing DSS from MIS.

1.2.3. A Set of Capabilities Expected From a DSS

A primary question still remains: What are the capabilities that a good DSS should possess?

This can be analyzed through some performance objectives. The performance objectives defined by Carlson and Sprague(9) will be reviewed here. But, it should be noted that no specific DSS will be required to satisfy all six of the performance measures stated here, since any specific DSS will be very much dependent on the task, the organizational environment and the decision-maker(s) involved. However, as a group, the following objectives represent a set of capabilities that determine the value of the DSS concept from the manager/user point of view:

(1) A DSS should support semi-structured and unstructured decisions as well as structured ones.

Gorry and Scott Morton(2) claimed that most of the computer support that existed by 1970's was for structured decisions, that some work was under way for supporting semi-structured decisions, but that unstructured decisions were completely left out. They argued that, it is the semi-structured and unstructured decisions that are of greatest concern to decision makers.

However, it should be kept in mind that the concept of "structure" in decision-making is heavily dependent on the cognitive style and approach to problem solving of the decision-maker.

(2) A DSS should provide support for users at all levels, assisting in integration between the levels whenever appropriate.

Following Anthony(13) decision levels can be classified as:

(i) Strategic Planning: Decisions related to setting policies, choosing objectives and selecting resources.

(ii) Management Control: Decisions related to assuring effectiveness in acquisition and use of resources.

(iii) Operational Control: Decisions related to assuring effectiveness in performing operations.

(iv) Operational Performance: Decisions that are made in performing the operations.

(3) A DSS should support the communication between decision makers so as to support interdependent decision - making.

Hackathorn and Keen(14) define three decision types:

(i) Independent: A decision-maker has full responsibility and authority to make a complete implementable decision.

(ii) Sequential interdependent: A decision-maker makes part of a decision which is passed on to someone else.

(iii) Pooled interdependent: The decision must result from negotiation and interaction among decision-makers.

(4) DSS should support all phases of the decision making process.

A popular model of decision-making with three steps is given by Simon(10):

(i) Intelligence: Searching the environment for conditions calling for decisions. Raw data are obtained, processed and examined for clues that may identify problems.

(ii) Design: Inventing, developing and analyzing possible courses of action. This involves processes to understand the problem, generate solutions and test solutions for feasibility.

(iii) Choice: Selecting a particular course of action from those available.

Implementation phase can be added to this sequence as the fourth phase.

The cycle of phases, however, is more complex than the sequence suggests. At any given level, subproblems that in turn have their intelligence, design and choice phases can be encountered. In this structure it can be seen that MIS and TPS have their contribution in intelligence phase, whereas MS/OR contribute in choice phase. By adding support at design and implementation phases, DSS completes and integrates these decision phases.

(5) A DSS should support a variety of decision-making processes but not be dependent on anyone.

There is no universally accepted model of decision-making process. Simon's model is only one categorization and a great variety of decision-making processes can be found in studies of decision-making.

Furthermore, a specific decision may be of a different type, in different organizations, at different times or for different decision-makers.

In fact, there has been some work on cognitive styles to drive operational guidelines for DSS design, i.e. regression models derived from a manager's past behavior to serve as a basis for future managerial decisions(15). However, this approach neglects the dynamic nature of the decision environment. If a DSS is designed for a specific type of decision and a specific decision-maker any change in them requires a change in the DSS to accommodate new conditions and leads to increased cost.

The effort should be toward creating a DSS that is flexible, friendly and provides a variety of options, so that a priori determination of the user's style as a basis for identifying the most appropriate design becomes irrelevant(16).

In short, DSS should be process independent and user-driven (or controlled). The term "user controlled" is used in the sense that the decision-maker is allowed to enter and use the DSS at any point in the decision process. Process flexibility can be obtained by reversing (inverting) model functions, i.e., treating decision variables as both input and output variables(11).

(6) *A DSS should be easy to use.*

It should be kept in mind that the aim is to help the decision-maker who is often a non-computer person.

1.2.4. The Development Approach for DSS

DSS require a unique approach to system analysis and design, because of a variety of reasons that may be encountered in a decision process(23):

(i) The designer or the user may be unable or unwilling to provide functional specifications and procedures, depending on the structure level of the task.

(ii) Users may not know what they want and the designers may not understand what they need or can accept; and initial system must be built to give users something concrete to react to.

(iii) User's concepts of the task or decision situation will be shaped by the DSS. The system stimulates learning and new insights, which in turn stimulate new uses and the need for new functions in the system.

(iv) The intended users of the system may handle the task in a variety of ways, or differ in the way they think to a degree that prevents standardization.

Items (i) and (iv) state that there is no well-defined process and the DSS should be process-independent. Item (iii) introduces the idea of an iterative design approach. Furthermore, while (iii) states that DSS shapes the user, (iv) equally suggests that the user shapes the DSS bringing forth the need for an adaptive design procedure. These issues will be discussed in the following paragraphs.

A user-oriented, process-independent design approach called ROMC is developed in works by Carlson and Sprague(9,24). The approach is based on defining a set of "Representations" that decision-makers use to conceptualize problems, "Operations" on those Representations, "Memory Aids" to support the use of Representations and Operations, and "Control Mechanisms" to apply different styles and skills. Different Representations, Operations, Memory Aids and Control Mechanisms may be required for all three decision phases of intelligence, design and choice.

Moore and Chang draw attention to the dynamic nature of the decision environments (p.11 of (11)):

"An important characteristic shared by all computer-based information systems is the need for periodic re-structuring, updating or expansion activities. For a variety of reasons-changing needs, earlier mis-specifications, revised context, change in capacity, newer technology, etc-all systems periodically under go such redirective activities. Without such activities, the system's usefulness would decline rapidly -hence, these changes are essentially mandatory. The periodicity of these operations is said to be shorter for DSS than other types of systems. In particular, a TPS might be rewritten every 3-5 years to synchronize with changes in the underlying operational hardware, and MIS expanded every 1-2 years to handle new requirements and regulations. A DSS could change

every few days or weeks, particularly during early phases of implementation and use".

Thus flexibility at moderate cost is a very important issue for DSS. This makes the traditional development life cycle approach which implicitly assumes a static decision environment inappropriate in DSS development. It is impractically time consuming and costly, and pre specification and consensus among clients concerning the desired system is difficult to achieve.

So, an iterative design procedure combining the typical steps of development life cycle approach (documentation of existing system, logical system design, physical system design, programming the new system and implementation), into a single step which is iteratively repeated, is suggested.

In this way, DSS will be built with short, rapid iterations, receiving feedback from users to ensure that development is proceeding correctly. DSS must be developed to permit quick and easy changes to accomodate the dynamic nature of the problem environment. These issues are discussed in detail in (9), (11) and (25).

User participation during development iterations of a DSS is an important factor which reduces the difficulties that may be encountered in implementation stages. Another direction of research in DSS literature, investigates the benefits of user involvement in system development(26,27,28, 29).

1.2.5. The Components of DSS

Alter(30) surveyed 56 DSS and divided them into two general categories: Data-oriented systems and model-oriented

systems. The data-oriented systems consist of systems for data retrieval, analysis and presentation, Both generalized and special purpose software are included in this category. The model-oriented systems provide accounting representational, optimization or suggestion models to help in decision-making (see Figure 1.1). The characteristics of these decision support system types are given on Table 1.2.

FIGURE 1.1- Data-oriented us Model-oriented DSS types(30)

There are many opinions on why data-oriented systems and model-oriented systems have not had much success in supporting decision-making, either ceasing to be used or being used for routine report generation rather than for direct support of decision makers. In general, the main problem seems to be a mismatch between the capabilities of these DSS and the requirements of the decision or decision-making.

This idea is viewed as follows in this study: The conceptual model is the problem as perceived by the decision-maker as a result of the intelligence activity. The modelling capabilities of DSS transform this conceptual model into a formal one. As the difference between the structure levels of the conceptual and formal models increases, the implementation of the solution generated by the formal model becomes harder,

CHARACTERISTICS	DECISION SUPPORT SYSTEM TYPES						
	A FILE DRAWER	B DATA ANALYSIS	C ANALYSIS INFORMATION	D ACCOUNTING	E REPRESENTATIONAL	F. OPTIMIZATION	G SUGGESTION
TYPE OF TASK	operational	operational or analysis	analysis	planning	planning	planning	operational

TABLE 1.2 CHARACTERISTICS OF PARTICULAR DECISION SUPPORT SYSTEM TYPES

requiring persuasion and additional transformation efforts. However, if the DSS supports the design and implementation activities as well as intelligence and choice activities by allowing the managerial judgements to be processed by the system and the user to gain insight to the problem through interactive supporting, the model rigidity will be reduced, the differences in the levels of structuredness of the conceptual and formal models will be reduced and the solution will be more readily applicable, reducing the implementation efforts. This can be achieved by attaching equal importance in the design of DSS to its three major components: The dialog, data and model subsystems.

(1) The Dialog Subsystem

The dialog subsystem consists of the user, the input and output media and the software. The dialog component meets the representation and control mechanism requirement of the DSS, by presenting DSS outputs to the users and collects user inputs to the DSS.

Dialog styles describe the nature of the interface between the system and the user. The choice of a particular style depends on the trade-offs on usability of the DSS versus the hardware and development costs(31).

(2) The Data Subsystem

The data subsystem consists of a data base and a data base management system, defined as a collection of programs used to create, maintain, access, update and protect one or more data bases.

The data base can be constructed using one of the data structures that can be found in data base literature, i.e., lists, tables, relations, hierarchies and networks(32).

The data base management system should provide(9):

- (i) the ability to combine a variety of data sources through a data capture and extraction process;
- (ii) the ability to add or delete data sources quickly and easily;
- (iii) the ability to portray logical data structures in user terms so that the user understands what is available and can specify needed additions and deletions;
- (iv) the ability to handle personal and unofficial data so that the user can experiment with alternatives based on personal judgement;
- (v) the ability to manage this wide variety of data with a full range of data management function.

The main features of data management for DSS is discussed in(33).

(3) *The Model Subsystem*

DSS integrates analysis procedures and decision models into the data base and dialog capabilities. This full integration is necessary to support decision-making activities such as projection, deduction, creation and comparison of alternatives which require close interaction and rapid feedback between the decision-maker and the computer, with strong and flexible control mechanisms. To provide these capabilities, the modelling component of the DSS must have a "model base" developed in modular structure and a comprehensive set of model base management functions.

During the literature survey of this study a number of specific DSS were studied. This section will be concluded by mentioning a few of them, just for the purpose of giving examples. They are not claimed to be typical or representative for the DSS concept.

(i) A DSS for urban growth management developed by the Dept. of City and Regional Planning in Ohio State University(18).

The DSS is based on a multi-criteria framework that integrates several socio-economic, physical planning and urban design processes. The integrated framework is seen as consisting of an interaction of a data base, projections and forecasts, impact analyses, decision analysis, and political sensitivity analysis.

(ii) Geodata Analysis and Display System (GADS) developed by the IBM Research Lab in San Jose, California(19).

It is an interactive system with strong graphic display and "user-friendly" characteristics to enable non-computer people to access, display and analyze data that have geographic content and meaning. It was used for 17 specific decisions, such as police personnel allocation application, school district planning, etc.

(iii) An Interactive Media Decision Support System(20).

It is an interactive, terminal based DSS which manages a large data base and provides many models that aid the advertising decision maker in media planning decisions such as establishing a desired market, finding media which reach that market, and allocating advertising funds to these media.

(iv) A Model-Directed Information System for Management of the Federal Courts(21).

To satisfy the diverse information needs of federal courts a family of information management systems has been developed, based upon formal mathematical models of judicial case processing embedded in interactive data base information systems for case tracking and case load management.

(v) A DSS for Ski Area Design(17).

Designing a ski area is based on a decision process with many feasible solutions involving a host of simple calculations, supported by expert judgements, and not subject to mathematical optimization. The issue of creating a process-flexible DSS has been considered in this study.

(vi) An Overall Interactive Computer-Based System for Petkim-Aliaga Complex(22).

This is an overall system design aiming to create an organizational and operational structure for efficient management of production activities in Petkim Aliaga Complex which is still in foundation phase.

1.3. NEED FOR A DSS CAPABILITY FOR QC

In Section 1.1.2. it was pointed that QC is not well understood as a management tool, and there is a lack of understanding of the statistical quality control techniques. Most of the managers preferred using their experience and judgements in solving the problems, because they cannot conceptualize formal models and the solutions generated by formal models can be difficult to implement.

Therefore, the first thing needed is a tool which helps filling this gap between the formal QC methods and the decision maker's understanding of them. Such a tool, should improve the decision-making process of the user by making him use scientific management approach to problems.

Furthermore, it should be friendly to the user. It should allow him use his experience and judgements on the subject in generating alternative solutions to the problem and in finding an "implementable" solution among them.

Such a support on decision making in QC, is possible through the use of a DSS, which satisfies the characteristics given by Carlson and Sprague(2):

(i) A DSS in QC supports decisions which are not well-defined in the minds of the decision makers. Since the concept of unstructuredness is subjective, a problem can only be structured "with regard to" a particular decision maker, or a well-defined set of decision-makers.

In our country, QC related decision problems can often be regarded as "unstructured" because the decision-makers do not have the habit of using scientific approach when trying to solve them.

(ii) A DSS in QC should combine the use of statistical, analytical or representational models with flexible data access and retrieval functions. This should be done in a way to allow the user to experiment with the QC system, to integrate his judgements in the solution procedure, and to learn about the system while doing these.

(iii) A DSS in QC should focus on features that makes it easy to use by non-computer people in an interactive mode.

(iv) A DSS in QC should be flexible and adaptable to changes in the QC environment and in the decision-making approach of the user which is expected to improve through the use of the DSS.

In the following chapters of this study, a specific DSS designed for QC will be explained. In Chapter II the specific decision taken into consideration and the way it is supported by the "Quality Control Decision Support System (QCDSS)" will be discussed. In Chapter III, an application of QCDSS in a light-bulb factory will be described in detail. Lastly, in Chapter IV, some concluding remarks will be made, and some possible extensions to QCDSS will be mentioned.

II. A DECISION SUPPORT SYSTEM FOR QUALITY CONTROL

Quality control function in an industrial organization is carried on through various decisions ranging from short to long range taken at various levels of the management.

In this study, a specific class of them, decisions related to the remedy of chronic quality problems are taken into consideration.

In this chapter, these decisions and the DSS designed to support them will be discussed.

2.1. THE SPECIFIC DECISION

Quality activities held in a QC department are concerned with both sporadic and chronic quality problems.

A sporadic problem is a sudden adverse change in the quality performance, requiring remedy through restoring the standard performance(34). The inspection plan is utilized for this purpose-that is, to control production in all stages by measuring actual quality performance, comparing it with standard and acting on the difference.

A chronic problem, on the other hand, is a long standing adverse situation, requiring remedy through changing the existing system. Since ways to do better than the standard should be found, these problems are often difficult to solve. Each case having different characteristics, it is very hard for the decision maker(s) to state a general, structured solution procedure when confronting with the problem. All these difficulties make most of the industrial organizations accept chronic problems as inevitable. Furthermore, firefighting on sporadic problems may take continuing priority, although larger savings are possible on chronic problems.

The essential features of chronic problems that would make a DSS capability a valuable and necessary tool can be listed as follows:

(i) As explained above, the decision makers have a kind of intimidation for this kind of problems. Therefore, a supporting tool which encourage interest and efforts towards the solution of chronic problems, by making the user understand the underlying conditions in the production would be a great help. Since gaining insights for the general QC system as well as the problem is required, this support should offer a learning process, i.e., the ability of experimenting with the system. This feature can be handled by a DSS.

(ii) The problem can be identified through data analysis. But an MIS in traditional context is not sufficient in this case(3), because the problem is aperiodic in nature and the data analysis should be ad hoc. The problem should be "searched for", so instead of pre-formatted reports, reports of flexible content are required. This flexibility can be offered by a DSS.

(iii) The predictive and planning orientation of the problem necessitates some modeling capability in addition to data analysis capabilities. However, a classical optimization approach would be even more intimidating, especially because optimization models often cannot be conceptualized well enough by the decision makers (See Section 1.1.2 and Section 1.3).

On the other hand, the nature of the problem requires the use of some managerial judgement. Since the solution will impose a change in the system, a resistance to this change will come up in the implementation phase. So, in choosing the solution the problem should be judged with all its aspects: Financial, technological and social.

So a DSS capability which combines data, model and dialog capabilities is necessary (See Section 1.2.3). The necessity for a dialog component is inherent in all three of the issues discussed up to now.

(iv) Quality Control system as a decision environment is quite dynamic in nature. So, while classical approaches with static assumptions happen to be ineffective, the DSS concept with its great concern in adaptability is appropriate (See Section 1.2.2).

(v) If an overall DSS capability is planned to be installed in an organization using a staged development approach, the choice for the initial DSS is very important. It should address a recognized need with promise of early observable benefits. Thus, the users will be motivated and willing to participate, which means that the implementation will be easier and the risk of obsolescence will be smaller.

The solution to chronic quality problems offer high probability of observable benefits. So, it seems a good place

to start before building a general DSS to support all QC activities.

These are the main characteristics which justify the building of the DSS that will be described in the following sections of this study. The same characteristics and some more which will become apparent later in this chapter, are tried to be built into the DSS when designing it.

2.2. DECISION STEPS

Decision steps in finding remedy to chronic quality problems can be examined using the typical system analysis approach of five phases:

(i) Problem identification: Identification of the chronic problems accounting for the most of the losses related to quality.

(ii) Problem investigation: Closer investigation of important chronic quality problems for their causes.

(iii) Design of alternatives: Suggesting possible remedies for the discovered chronic quality problems.

(iv) Evaluation of alternatives: Estimation of the benefits possible from the suggested alternatives.

(v) Choice: Deciding which suggestion to implement.

Looking at the same decision using Simon's model(10), the first two steps fall into the "intelligence" phase, the third and the fourth steps make up the "design" phase, "choice" phase is the same.

Since chronic problems will require far-reaching investigation for possible causes and courses of action, the second and the third phases can be interdepartmental. Nevertheless, the first attack will come from the QC department, for most of the time.

Below those decision steps are explained in the context of the specific decision.

2.2.1. Problem Identification

The starting point for any quality improvement program is an investigation of the current quality performance, to bring chronic quality problems into daylight. This requires a cost oriented analysis which spots vital few problem areas amongst trivial many, and thus helps identifying opportunities for reducing quality costs. "Failure Analysis" can be regarded as a systematic Pareto analysis serving this purpose.

2.2.2. Problem Investigation

The emergence point of these important chronic quality problems should be found out by investigating whether they are related to machine or operator error or to the technology used, or the management, itself.

2.2.3. Design of Alternatives

According to the cause discovered in the second step, a number of changes in purchasing, maintenance and personnel policies, in machines, technology or production management can be suggested. The inspection plan can be changed in various ways, trying to take the problem in control.

2.2.4. Evaluation of Alternatives

Some of cost and status changes that will be caused by the suggested alternatives can be estimated using available data and the remaining can be estimated subjectively. Thus, the expected quality improvement can be compared with the required additional investment, personnel costs and other draw backs due to the change.

2.2.5. The Choice

Depending on the type of the problem and the precaution, the decision can be made within the Quality Control Department or at higher management levels.

2.3. THE POSITION OF THE SPECIFIC DSS IN THE OVERALL DECISION MECHANISM

The specific DSS developed in this study, which will be called QCDSS from now on, supports the decision discussed above in the Failure Analysis (Section 2.1.1) and in the estimation of possible consequences of suggested alternatives on costs and quality level. (Section 2.1.4). Furthermore, it provides the decision-maker with a framework within which he can generate his alternatives easily and quickly, thus it contributes to the design phase, too.

The Failure Analysis and cause investigation following it, can result in the launching of a quality improvement project aiming to get rid of the chronic problem(s) identified. Such a decision is a "pooled interdependent"(14) one, i.e., it will be taken by a group of managers from various departments as a result of some negotiation and interaction. And, it is a management control decision which will result in

a change in one or more of purchasing, maintenance, personnel or production management, in machines or the technology used or in the product, itself.

On the other hand, there may be cases when the discovered problem cannot be solved in this way, or the timing may not be appropriate for such a project to be started, or the cause of the problem may be unknown. In such a case, the inspection plan should be revised in order to get control of the newly discovered critical points or to reduce scrap and rework costs by detecting vital defects as early as possible. This is an "independent" decision which the QC department has to repeat at rather short intervals, and it is on "operational control" level.

Quality Control activities in an industrial organization can be classified in compliance with Gorry and Scott Morton's framework(12) as in Table 2.1. It can be seen on this figure that the components of QCDSS lie in Operational Control and Management Control columns.

Figure 2.1 gives another representation of the position of QCDSS in decision mechanism, this time together with the information network it is embedded in.

2.4. THE POSITION OF THE SPECIFIC DSS IN INFORMATION FLOW

The position of QCDSS in information flow has importance with regard to the ease in implementing it and the cost/benefit analysis.

Nearly all of the data requirements of QCDSS will be satisfied within the QC department. Only in calculating Quality costs there is need for some input data from the

TABLE 2.1- QC activities classified according to types of decisions and degree of decision structure

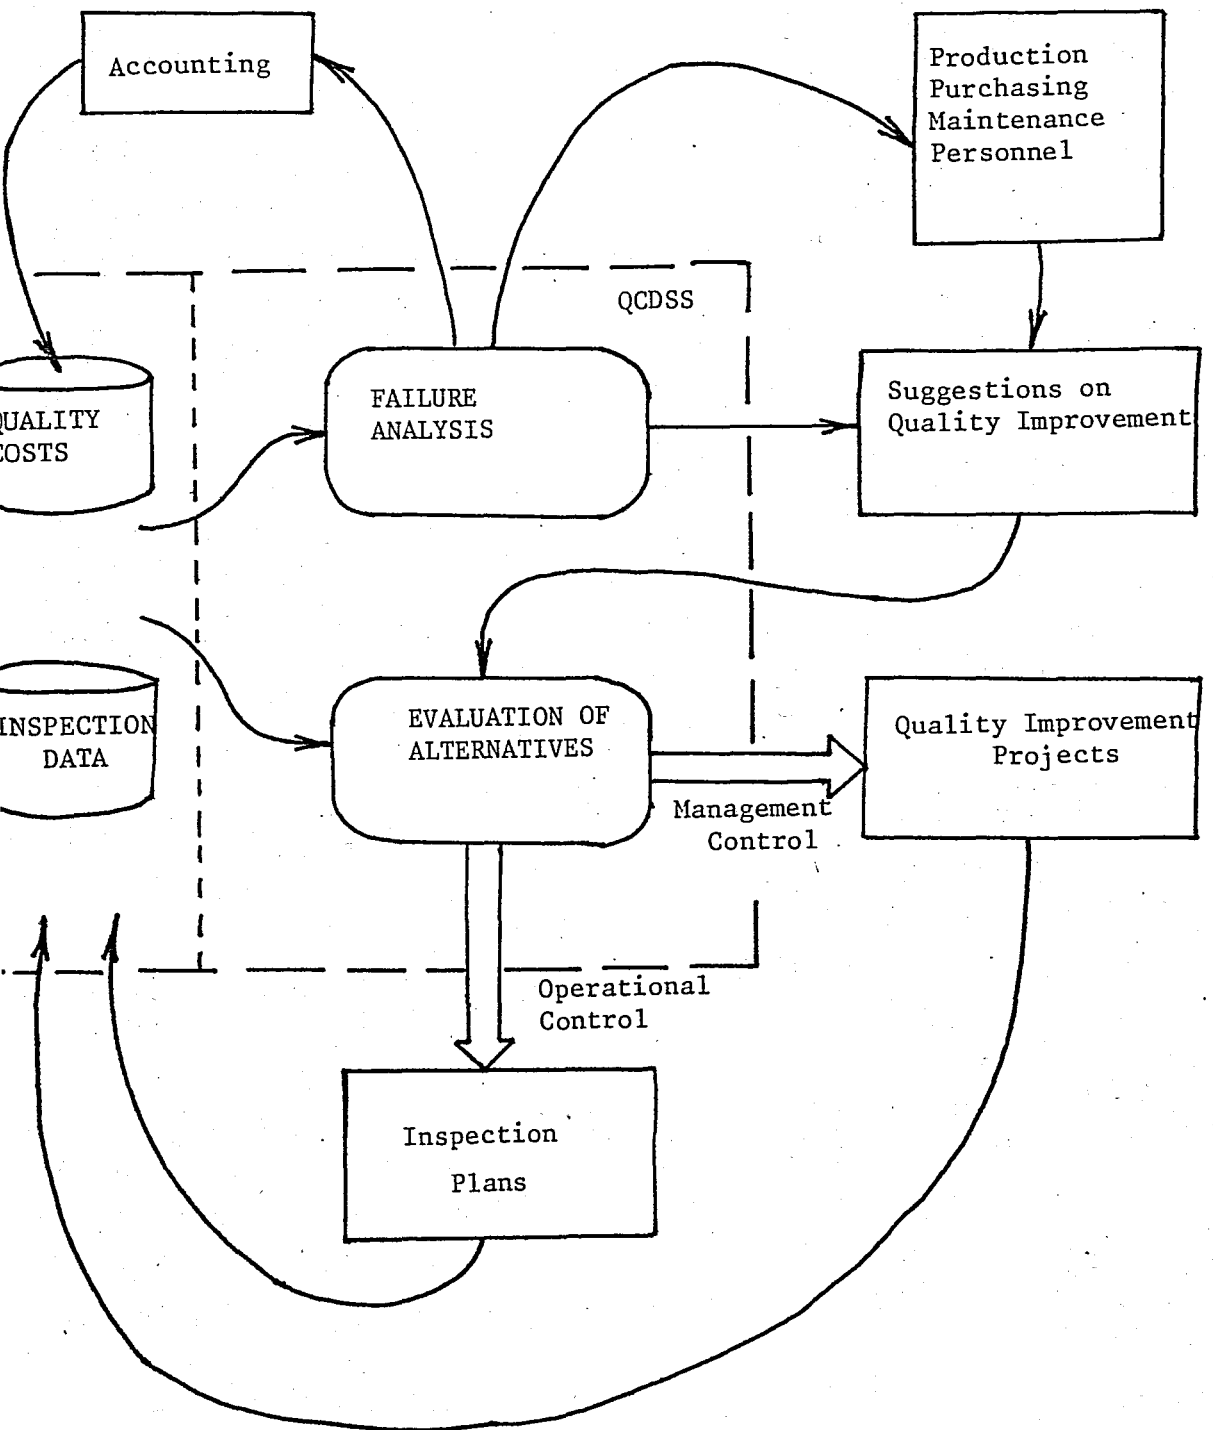

FIGURE 2.1- Position of QCDSS in the Decision Mechanism and in the Information Flow

Accounting department (See Figure 2.1). A description of the current inspection plan, daily inspection and scrap data and data on quality costs should normally be available in a QC department, anyway. Therefore QCDSS does not bring any additional burden in data collection. The data base is designed as easy to use as possible, and moreover, in a way to facilitate adaptation to changes in the quality control system. These issues which will be discussed in detail in Section 3.2.1 are factors that decrease the cost of implementing such a system.

Although information that can be received from production, maintenance, purchasing and personnel departments, i.e., maintenance programs, new purchasing contracts, etc., do not reside in the system, they can be reflected to the decision-making process by the decision-maker through the use of flexible dialog capability of QCDSS.

QCDSS, beyond its main purpose, produces many kinds of information. Most of the reports to be distributed to the Production Department and to upper management by the QC Department can be prepared by using the report generating capability of QCDSS.

Moreover, Failure Analysis can generate some valuable information for production, maintenance, purchasing, and personnel departments. By adding a periodic pre-formatted report generator, the system can release exception reports and historical information for managerial review.

Although beyond the real scope of a DSS, such capabilities are important since they will increase the benefits obtained from the system and thus its cost-effectiveness and value in the eyes of the management.

III. AN APPLICATION IN A LIGHT BULB FACTORY

The Specific QCDSS described in Chapter II is designed for the Quality Control Department of a light bulb manufacturing company. In this chapter, bulb manufacturing and the present QC application in this factory will be described first, and then the interactive computer system developed will be discussed in detail.

3.1. CURRENT QC APPLICATION IN LIGHT BULB MANUFACTURING

The light bulb factory mentioned above, works on three product groups producing a variety of incandescent, fluorescent and mercury vapor lamps.

Flowcharts for manufacturing processes of incandescent, fluorescent and mercury vapor bulbs are given in Figures 3.1, 3.2 and 3.3, respectively.

In the present QC application, the focus is on incandescent production and records are complete only for this product group. Therefore, here, the QC application on incandescent production will be described. For the same reason, incandescent production is a natural starting point for the implementation of QCDSS and although the system is designed in a way that can handle any number of product groups, all

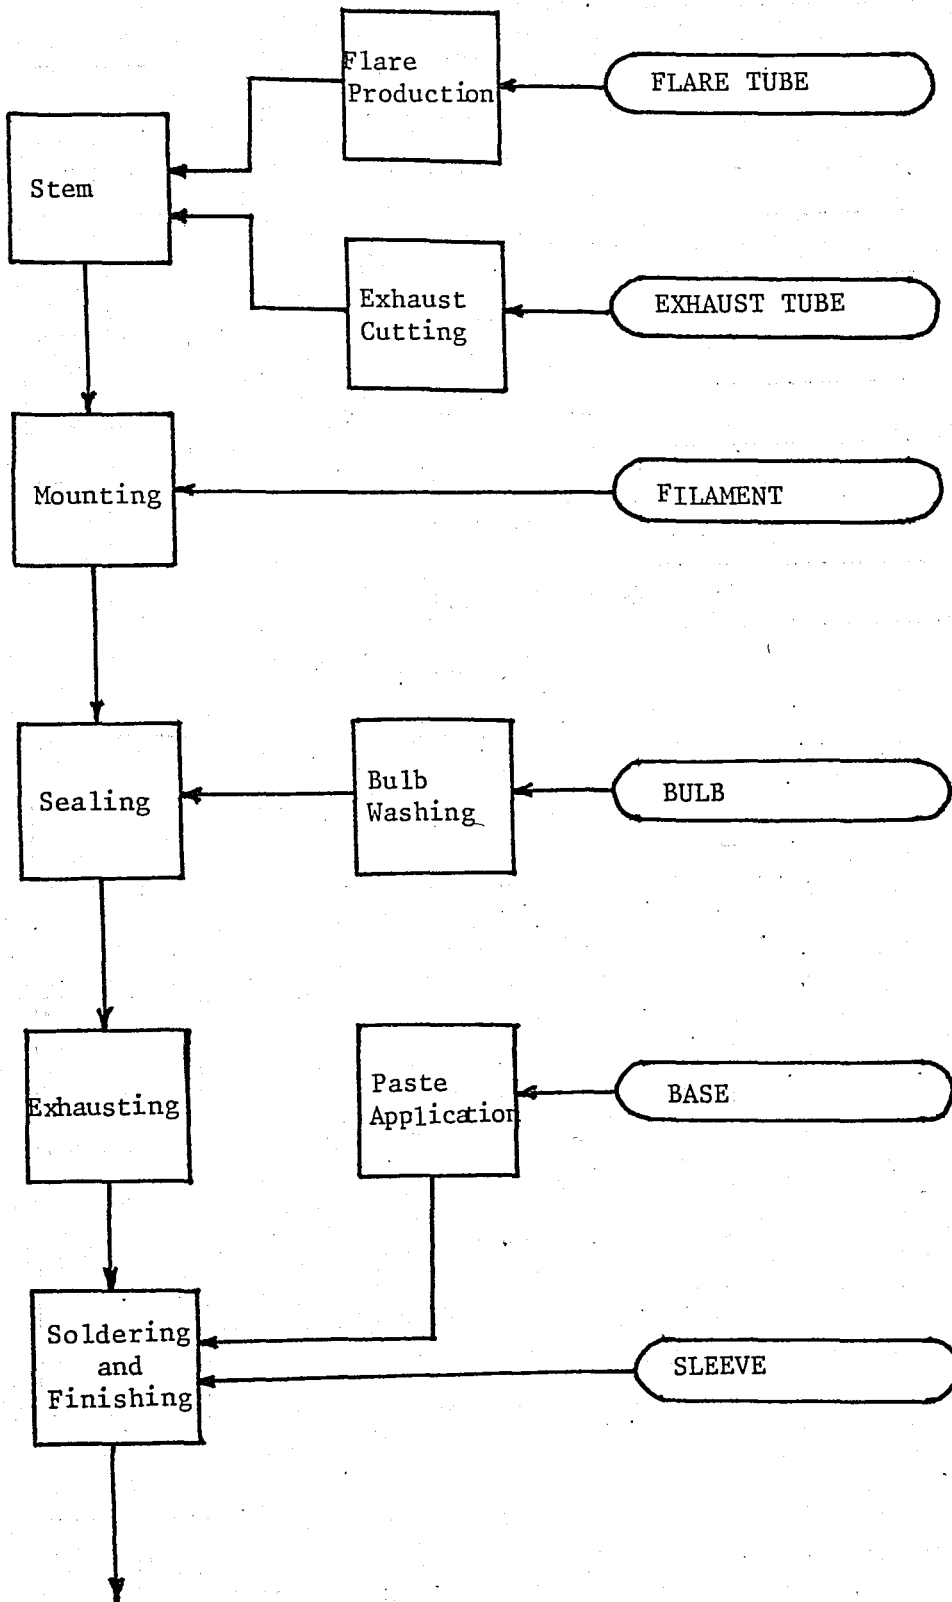

FIGURE 3.1- Incandescent Light-bulb Manufacture

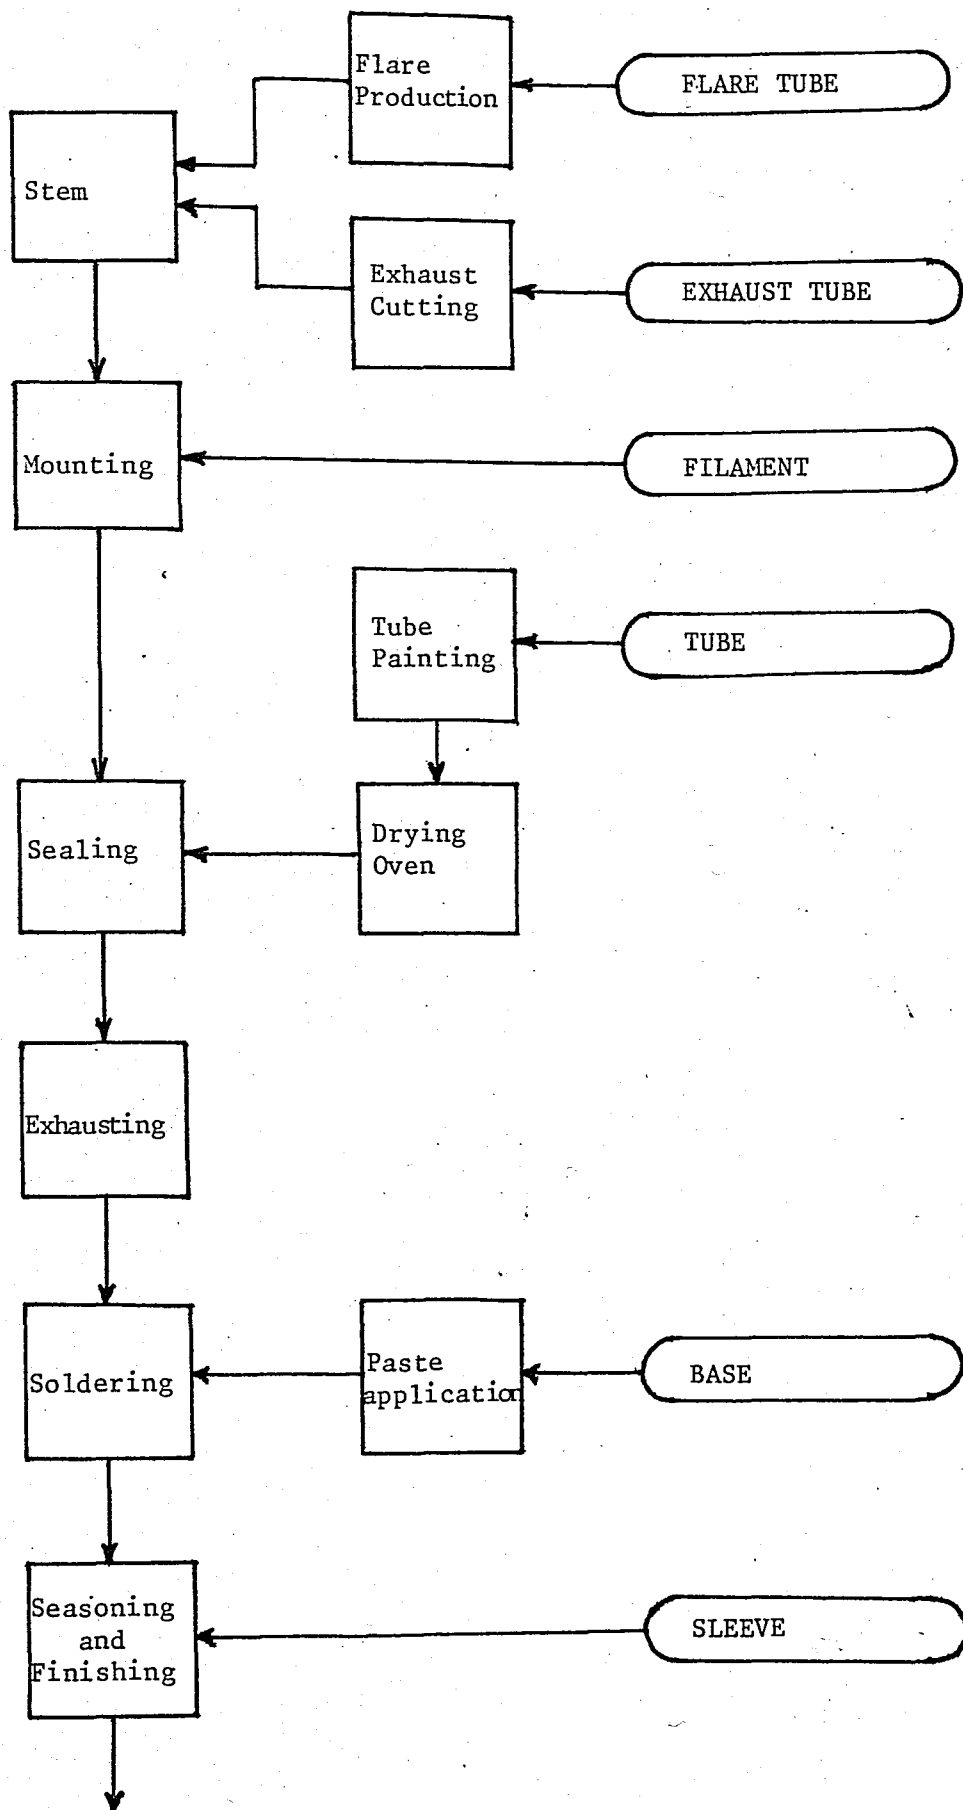

FIGURE 3.2- Fluorescent Lamp Manufacture

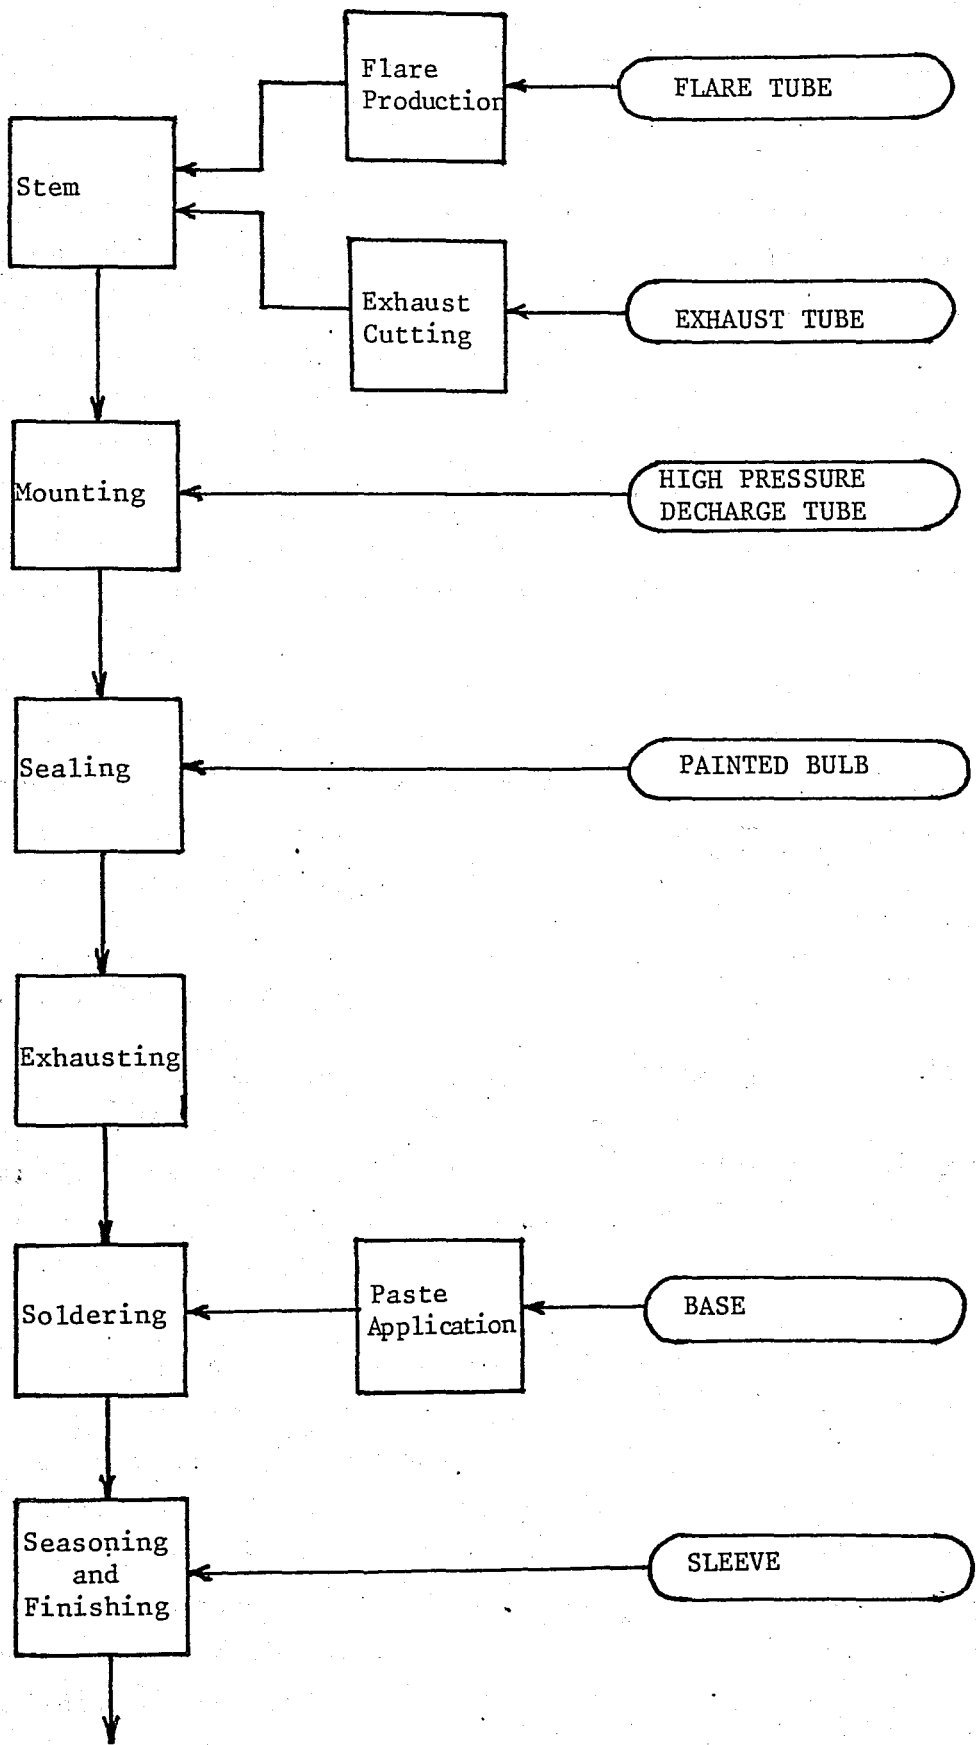

FIGURE 3.3- Mercury Vapor Lamp Manufacture

the examples given further in this study will be on incandescent production.

There are five main operations in incandescent production: Stem production, mounting, sealing, exhausting and finishing. Sealing and exhausting operations are conducted on a composite machine and from now on the term "Sealex" will be used for those operations.

A line consisting of these four machines is called a machine group. For each production type there are a number of machine groups working for two or three shifts.

The main characteristic of bulb production is that it is a continuous production. The number of bulbs produced is dependent on the particular machine group and the shift, but roughly speaking, it is about 10-15 thousand bulbs per shift on a machine group.

3.1.1. In-Process Inspection

During production process, inspection is made on two control stations on each machine group. First control station is after mounting and is called "Stem and Mount Control". Second station is after the last operation and it is called "Sealex and Finishing Control".

All controls made during production are attribute controls where bulbs are inspected visually. Inspection is made by visiting the control stations at certain time intervals and picking defective bulbs until a box of 120 nondefective bulbs is produced. Each time, the defectives caught are recorded by defect type on defective report sheets. By the end of the shift, the numbers are summed to get daily defective numbers.

Figure 3.4 gives main types of defectives that may be produced at each operation. The control stations and main defective types observed at these stations are shown on Figure 3.5. A typical characteristic of bulb production is that, a defective produced at any stage can be caught at any one of the following control stations.

An essential feature of the control procedure is that it is not a rectifying type of procedure, i.e., whenever some sign of low quality production is observed during inspection, the production is not stopped to screen the items produced, but the operator is made aware of the situation to make necessary adjustments, aiming to restore quality of future production.

Thus, although this inspection procedure is not a control chart application, it certainly has certain features of control chart applications.

3.1.2. Finished Product Inspection

After being aged for three days, a sample of 5 % is taken from finished incandescent bulbs. This sample is collected by randomly picking 6 bulbs out of 120 of each box produced, and thus forming a sample box for every 20 production boxes.

"Glow" and "Light" tests are performed on the sample and the defectives caught are recorded. All of the remaining production is taken to glow test, thus 100 % inspection is applied for glow test. However, glow test is not sufficient to screen all defective bulbs. So, light test is carried on for those portions of the production which are represented by the sample boxes rejected in light control. Rejection of a sample box in light control depends on the seriousness of

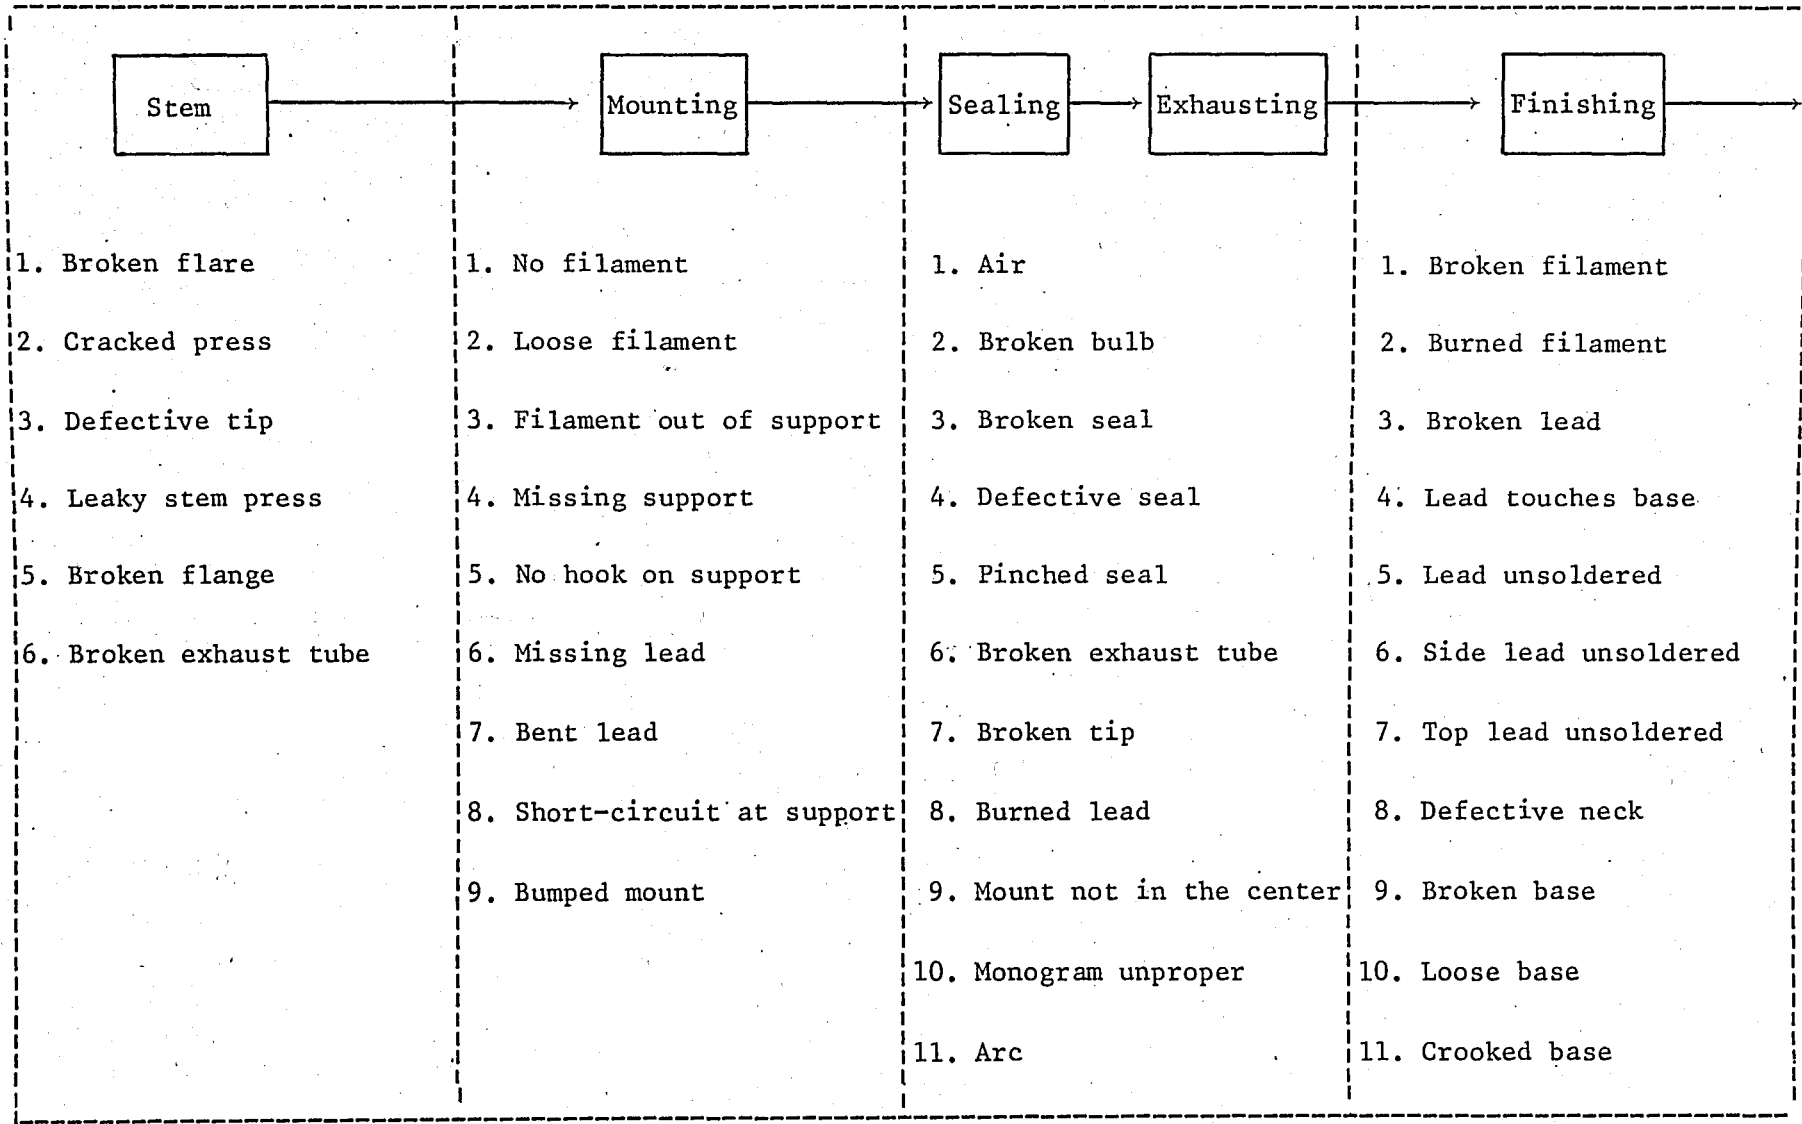

FIGURE 3.4- Main defective types produced at each operation

STEM AND MOUNT CONTROL

- Rework:

- 1. Bumped mount

- Scrap:

- 1. Broken flare
- 2. Cracked press
- 3. No filament
- 4. Loose filament
- 5. Filament out of support
- 6. Missing support
- 7. No hook on support
- 8. Missing lead

SEALEX AND FINISHING CONTROL

- Rework

- 1. Burned lead
- 2. Side lead unsoldered
- 3. Top lead unsoldered

- Scrap:

- 1. Broken flare
- 2. Cracked press
- 3. Defective tip
- 4. Leaky stem press
- 5. Bent lead
- 6. Bumped mount
- 7. Burned filament
- 8. Broken bulb
- 9. Broken seal

- 11. Broken exhaust tube
- 12. Air
- 13. Defective tip
- 14. Crooked base

FIGURE 3.5- Control Stations in Incandescent Lamp Production

defect types observed. In the present application, this decision is completely intuitive and does not comply with any preset criteria. However, in the newly developed system, it is proposed to assign certain penalty points to each class of defectives and to reject a sample box whenever the sum of penalty points reaches a specified limit. Table 3.1 shows the seriousness classes and the suggested penalty points.

TABLE 3.1- Table of seriousness classes for defect types

Seriousness Code	Seriousness Definition	Penalty Points
B1	Slightly mars the lamp appearance	2
B2	Materially mars the appearance	5
C1	Slightly effects performance	10
C2	Materially effects performance	25
D	Lamp will not operate	50
E	Lamp may damage surrounding equipment, persons etc.	150

3.1.3. Laboratory Tests

In laboratory a number of photometric tests such as life tests, and measurements of electrical characteristics are carried on samples of finished bulbs. The results of these tests are submitted to upper management as quarterly reports.

Laboratory test are excluded from this study.

3.2. THE PROPOSED SYSTEM: QCDSS

The proposed system has the three major components of a DSS: Data, Models and Dialog (See Figure 3.6).

(1) Data Subsystem

The data subsystem consists of data files and data base management software.

Data files are the inspection data files, quality costs files, defect types file and inspection plans file. These files will be discussed in detail in Section 3.2.1.

Data base management software consists of data input, file generation, update, listing, query and retrieval functions.

(2) Model Subsystem

The first model, which is developed to support problem identification phase is used as a systematic Pareto analysis model to be employed in the investigation of the current quality performance. It is called "Failure Analysis" model and described in Section 3.2.2.

The second model is a Monte-Carlo simulation type of model, to be used in the alternative evaluation phase of the decision, on a what-if basis. It estimates system parameters and calculates expected values for performance measures. This model which is called "Revision of the Inspection Plan" will be described in Section 3.2.3.

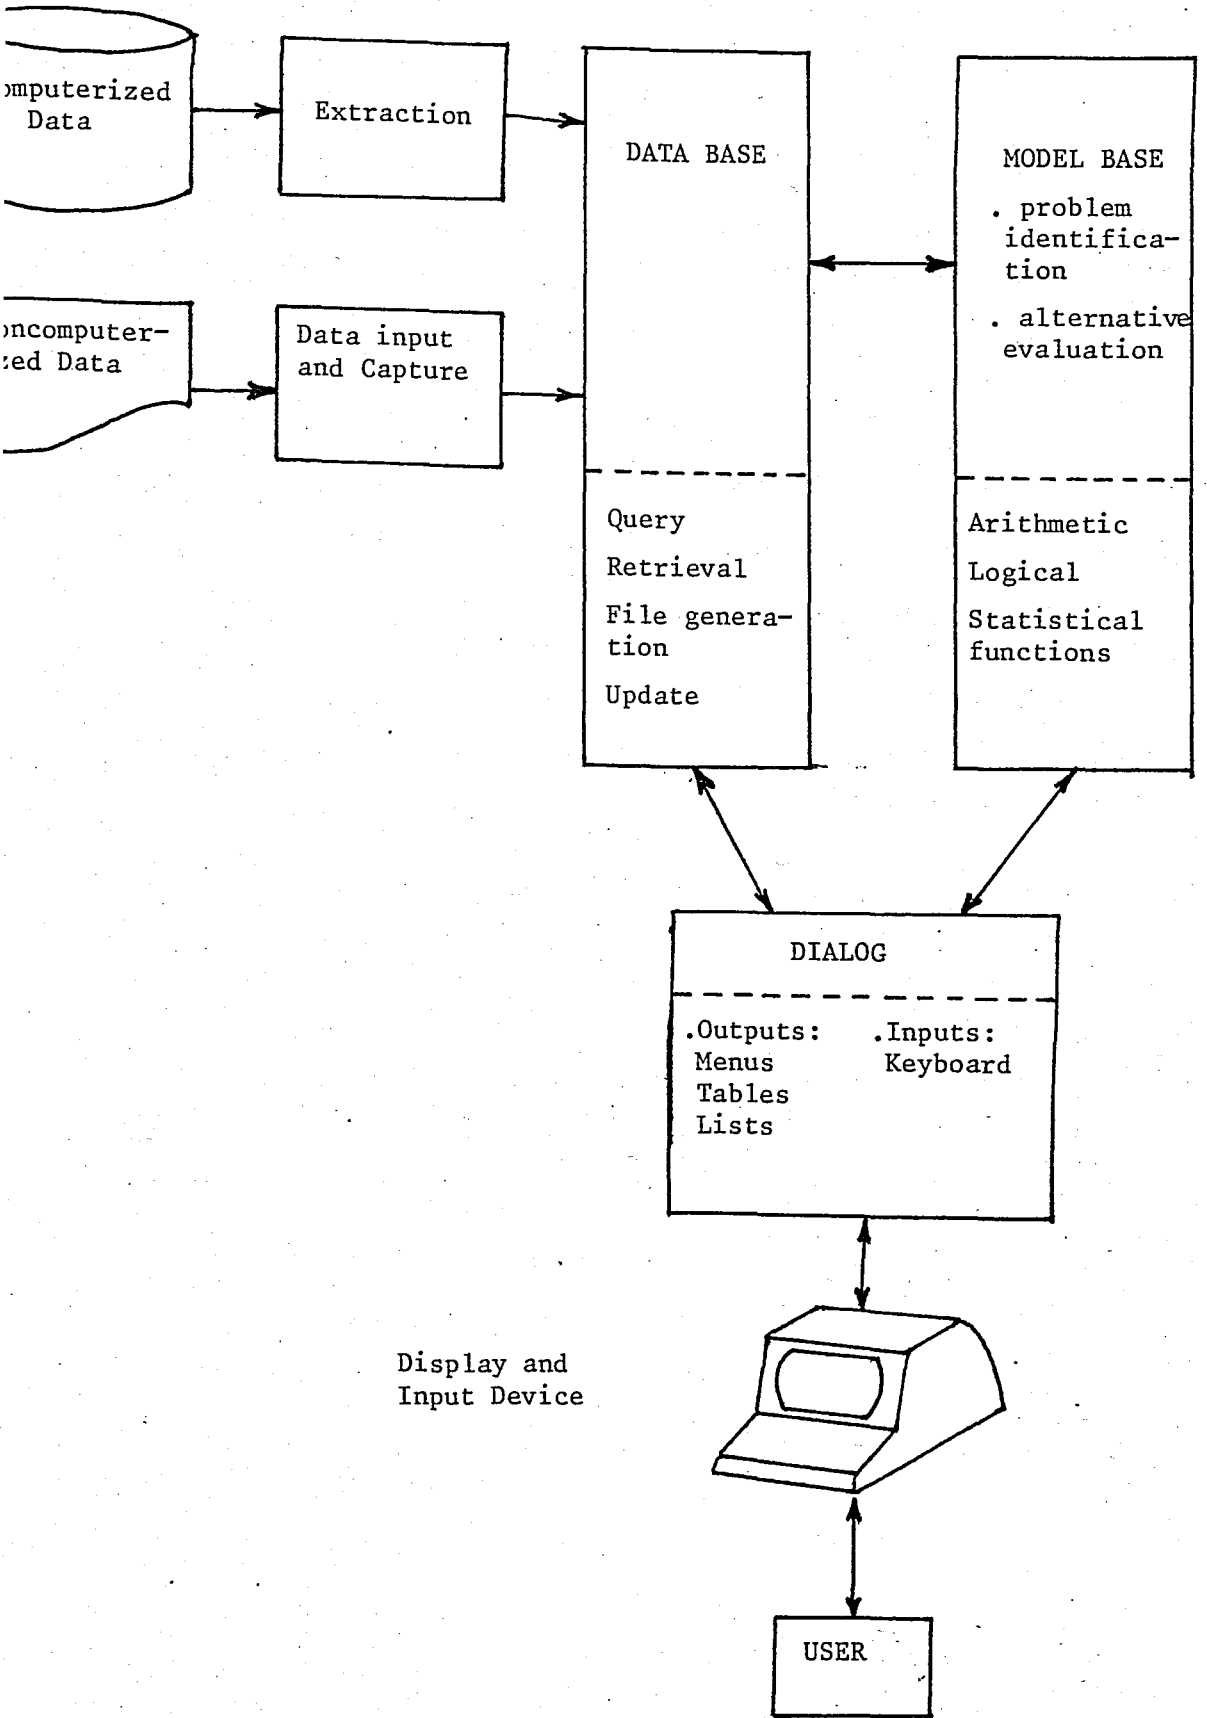

FIGURE 3.6- Components of QCDSS

(3) *The Dialog Subsystem*

The system is designed on Commodore 8065 microcomputer with full-screen graphics terminal and lineprinter as output media and the keyboard as the input medium.

QCDSS combines menu driven and question/answer dialog styles. The dialog is in Turkish.

The dialog subsystem produces output representations such as tables and reports. It enables the user to invoke and provide parameters for the operations. It supplies memory aids such as "libraries" for preserving intermediate results for later use, "links" for remembering data from libraries for reference while operating, and "profiles" to store default and status data. It provides some control aids such as error messages, warnings and the ability of changing the results of certain operations.

During the design of the dialog subsystem, it was aimed to minimize the number of input errors, to supply a wide variety of alternative choices at each decision point and to develop a system as easy as possible to use.

In the following sections it will become clearer how the dialog subsystem facilitates the mechanics of using QCDSS.

3.2.1. Data Files of QCDSS

Inspection Data files are the source files of QCDSS. Beyond them, there are a number of other files which can be called Support files. These are Quality cost files, Defect Types file and Inspection Plans file.

When designing these files, the main consideration has been that they should be adaptive to any change in the existing system. This is a very important issue, which will avoid the problem of the DSS becoming obsolete when a change occurs in the decision environment.

The second consideration taken into account was that these files should be designed in a way to allow utilization for different purposes, instead of being bound to the specific QCDSS.

(1) Inspection Data Files

For each product group, two inspection data files are designed:

- (i) In-process inspection data file
- (ii) Finished product inspection data file

Both are direct access files.

The raw inspection data, in other words the daily defective reports, will be input to the system everyday. During data input the system operates on this data adding to it some information-i.e. defective costs by type and total daily cost. This is done to reduce number of operations while the system is being used.

To minimize the data input errors and obtain high data reliability, various checks are made during data input. In addition to that, to make data input as easy as possible the design of file records are very similar to defective reports. Since a separate record sheet is used for every machine group/shift/control station combination, the file records are arranged in the same manner (See Figure 3.7).

*Record for the second control station on the i^{th} machine group/shift.

FIGURE 3.7- Contents of a record in In-process Inspection Data File

As a result of these efforts, data input procedure does not require any specially trained personnel.

Inspection data files are read by the help of an auxiliary file called "Description" file. This file describes the way records are arranged. In this way, the data files are independent of number of product groups, machine groups, shifts and control stations and this enables them to be easily adapted to any change in the existing QC system.

(2) *Quality Cost Files*

QCDSS uses quality cost figures as a measure when identifying problem areas and evaluating alternative precautions, since monetary terms are the most meaningful measure for the managers.

In order to do this, unit cost for every defect type is calculated. Defect cost is considered to have three components:

a) Material Cost: It is the total cost of material that will be wasted on a defective bulb when it is caught. For instance, when a defect of "loose filament" with code 222 is caught at Stem and Mounting Control, 1 exhaust tube, 1 flare, 2 leads, 1 support, and 1 filament are wasted.

b) Labor Cost: When calculating unit labor cost, if total labor cost is divided by total net production amount, then the labor spent for defectives is being distributed on non-defective products. However, when considering quality costs, the aim is to find out the real amount of labor spent on a bulb by the end of production process, so that when a defective bulb is caught, the amount of wasted labor will be known. Because of this, instead of using the method generally used by accounting departments,

the labor cost is calculated by using the following method:

Net amount of production	: A	units
Theoretical material cost(*)	: B	TL
Realized material cost(*)	: C	TL
Total shrinkage	: $D=C-B$	TL
Theoretical unit material cost	: $E=B/A$	TL/unit
Equivalent units to shrinkage	: $F=D/E$	units
Gross amount of production	: $G=A+F$	units
Total labor cost	: H	TL
Net unit cost of labor	: $I=H/G$	TL/units

(*) Unit material costs should be the same

However, since labor utilization at different machine groups are different, this net unit cost of labor is not sufficient. The unit cost of labor should be calculated separately for each machine group.

Total net labor cost	: $J=AxI$	TL
Net production for machine i	: a_i where $\sum_j a_j = A$	units
Planned production rate for machine i	: k_i	units/hour
Labor utilization index	: $\ell_i = a_i/k_i$	hours
Net labor cost assigned to machine i	: $m_i = J \times \ell_i / \sum_j \ell_j$	TL
Net unit labor cost for machine i	: $n_i = m_i/a_i$	TL/unit

Now, it should be found out how much of this net unit labor cost is added to the cost of a bulb at each production stage. In this way, labor cost of defective bulb will be assigned according to the stage it is caught.

For this distribution to be made, operation time and difficulty, number of workers and worker qualification at

each stage of production should be considered. It is observed that, on a machine group production stages do not differ significantly from these respects, therefore the unit labor cost can be distributed equally.

c) Indirect Production Costs: The indirect production cost to be assigned to a defective item is calculated by using a specified ratio (r) of the sum of material and labor costs of that defective item. This ratio is obtained by dividing total indirect production costs to the sum of total material and labor costs of the previous period.

The cost of a defective light bulb calculated in this way is dependent on the defect type and the stage the defective is caught. Therefore these cost figures by defect type are stored at four different files for four candidate control stations. In this way adaptation to any change in the locations of control stations will not be a problem.

These cost figures should be updated whenever necessary by using estimates of production amount, material cost, labor cost, and indirect production costs for that period.

(3) Defect Types File

The necessary information for all defect types observed in light bulb manufacturing is stored in a direct-access file. The contents of a record are shown on Figure 3.8. The key field is the defect code. The "related operation" is the production operation during which that particular defect is produced. "Seriousness class" indicates the class of the defect. (See Table 3.1).

Defect Code	Defect Description	Related Operation	Seriousness Class
101	Arc	Sealex	B1

FIGURE 3.9- Contents of a record in Inspection Plans File

(4) *Inspection Plans File*

This is a direct-access file where the current and the previous inspection plans are stored (See Figure 3.9). For each machine group/shift/operation combination there is a record. The inspection plan on that combination is indicated by a code, including a "no inspection" option.

3.2.2. Failure Analysis Module

Failure Analysis Module is developed to support the problem identification phase of the decision (Section 2.1.1).

It provides the decision maker with a variety of processed views of the data base aggregated from different angles.

This is done in an interactive mode. The user chooses the views -or, tables- he wants to see, one after the other in a way that leads him to a decision. How this is done is represented on Figure 3.10 and is explained below.

The program starts with an "Analysis Level Menu". As seen on Figure 3.11, analysis can be made on six levels. When designing these six levels, all views a decision maker may need during the analysis and the structure of production in the factory are taken into consideration.

In the "General" level the user can compare the performance on three product groups.

In the "Product Group" level he can examine a specific product group by its lamp types.

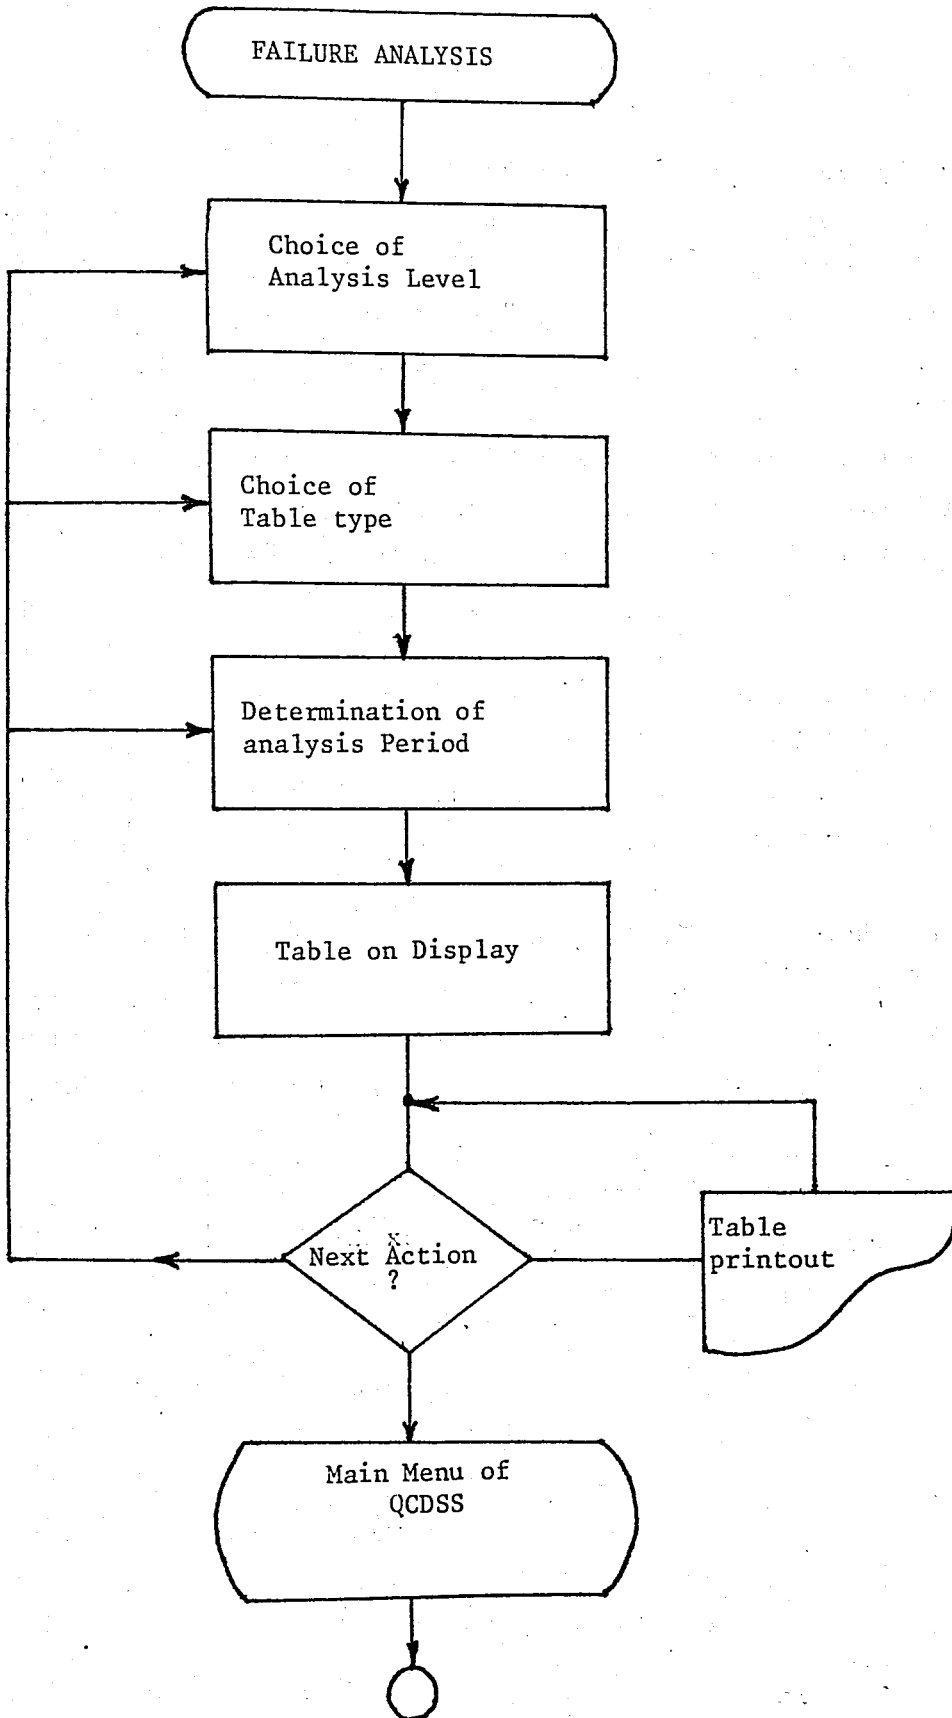

FIGURE 3.10- Failure Analysis Module as the User sees it

In the third level which is "Lamp type" both the product group and the lamp type are specified and the user can compare the performance in the control stations belonging to that combination. The term "lamp type" applies to the wattage of the light bulb.

The next level is the "Control Station". Here, the user can investigate the performance by machine group or by lamp type for a specific control station of a specific product group.

In the last two levels - "Control Station/Machine Group" and "Control Station/Lamp type" - everything being specified the window gets smaller and the user can observe the performance at a particular point in the production.

In this manner, as one comes down the menu, the scope of the analysis gets narrower. This enables the decision maker to start the analysis anywhere and then gradually focus on the problem he discovers.

QCDSS

- <7> End of Analysis

Choice ?—

FIGURE 3.11- Analysis Level Menu

After the analysis level is specified, it comes to the choice of the particular table. For this purpose, a separate "Table menu" is prepared for each analysis level and the alternatives provided to the user are listed.

On these "Table Menu"s three main types of tables are present:

(i) For the Overall Period: It is the aggregation of Information for the overall of a period specified by the decision maker.

(ii) Time-series: The analysis period is divided into time intervals of length specified by the decision maker. In this way, the quality performance changes during a particular period can be observed.

(iii) For the First Five Defect Types: On this type of table, detailed information on the five defect types observed in a specified period are given. These five defect types are the ones whose cost weight during the period are the highest. This table type can give important clues for cause investigation.

Second type of tables require additional parameters to get constructed.

First one is the type of information to be tabled. There are two alternatives:

- (i) defective percentage
- (ii) cost weight in percentage

Secondly the length of the time interval needs to be specified. There are three alternatives:

- (i) week
- (ii) month
- (iii) quarter

Please specify the Analysis Period ?—

- <1> Last -- weeks
- <2> Year to date
- <3> Beginning and end of period
will be specified

FIGURE 3.12- Determination of the Analysis Period

After choosing the table type, the decision maker specifies the analysis period. There are three alternative ways to do this and they can be seen on Figure 3.12.

Everything thus being specified the table is displayed to be examined by the decision-maker. He can also take a print-out if he wishes to.

As the next step, the decision maker may wish to see a new table at the same or a different level. This operation is repeated as many times as the decision maker wishes.

By the end of the analysis, the decision maker is expected to gain a clear notion of the current quality performance, spot the main problem areas and get some clues about the causes of problems.

Available table types for all six analysis levels are explained in Appendix A. It is aimed to give the decision maker as many alternatives as possible, but of course, a decision maker will use the ones that are most meaningful to him. This set of tables can be different from user to user.

In fact, after the system is implemented it will become apparent which tables are used most and whether the contents of the tables are sufficient. This experience may lead to the adaptation of the system to the decision maker's needs and cognitive style.

3.2.3. Revision of The Inspection Plan Module

In the fourth phase of the decision process which is the alternative evaluation phase (Section 2.1.4), the decision maker needs a tool that helps in estimating the consequences of any change in the existing system.

This module has been developed for this purpose. It gives the decision maker a measure for comparing various alternatives on a what-if basis, without any effort for an optimization. In fact, an optimization approach would hinder the integration of the experience and the judgements of the decision-maker, which can be very important for this case. Furthermore, such a technique would not permit user participation in alternative creation, making the system a black-box.

This module, however, allows the decision maker to apply his job specific experience and his own heuristics in creating and comparing alternatives. In this way, the decision-maker will gain a thorough understanding of the system behavior and will have the opportunity of experimenting with the system. Furthermore, the number of alternatives to be tried is not too many in real-life problems.

The module is designed to estimate the parameters of the current quality system in practice, get the decision variables from the user through alternative generation and calculate the expected values for performance measures using

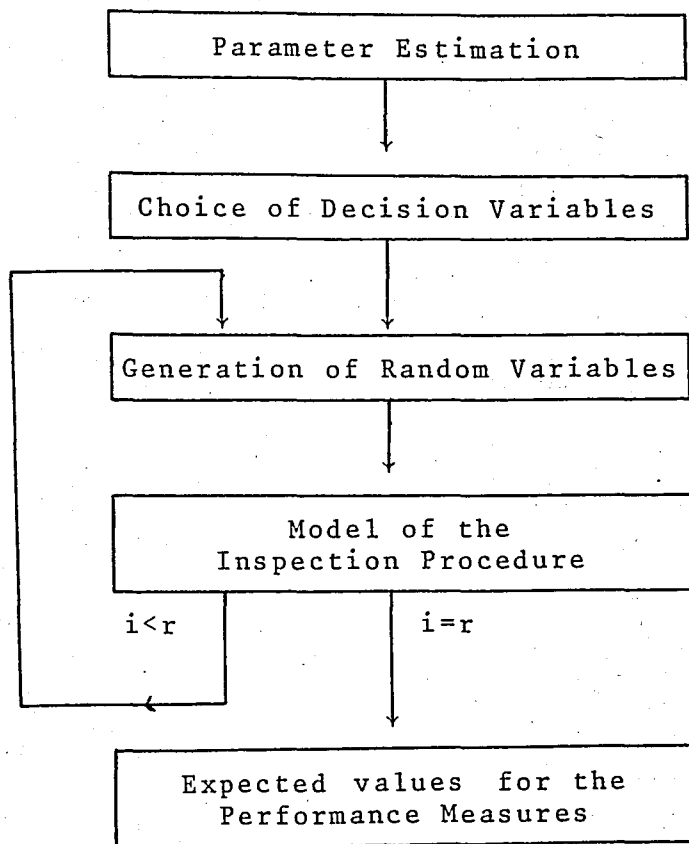

FIGURE 3.13- Monte-Carlo simulation model used in evaluating the alternatives

a Monte-Carlo simulation approach (See Figure 3.13). This cycle is repeated, each time preserving the results for future reference until the decision maker comes to a decision. Thus the model integrates and supports design and choice activities of the particular decision problem.

The mechanics of the model, as the user sees it, is represented in Figure 3.14.

The inspection procedure is modelled as in Figure 3.15. The model represents the existing inspection procedure as well as the alternative procedures that will be created by the user by changing the decision variables.

FIGURE 3.14- The Revision of the Inspection Plan Module as the user sees it.

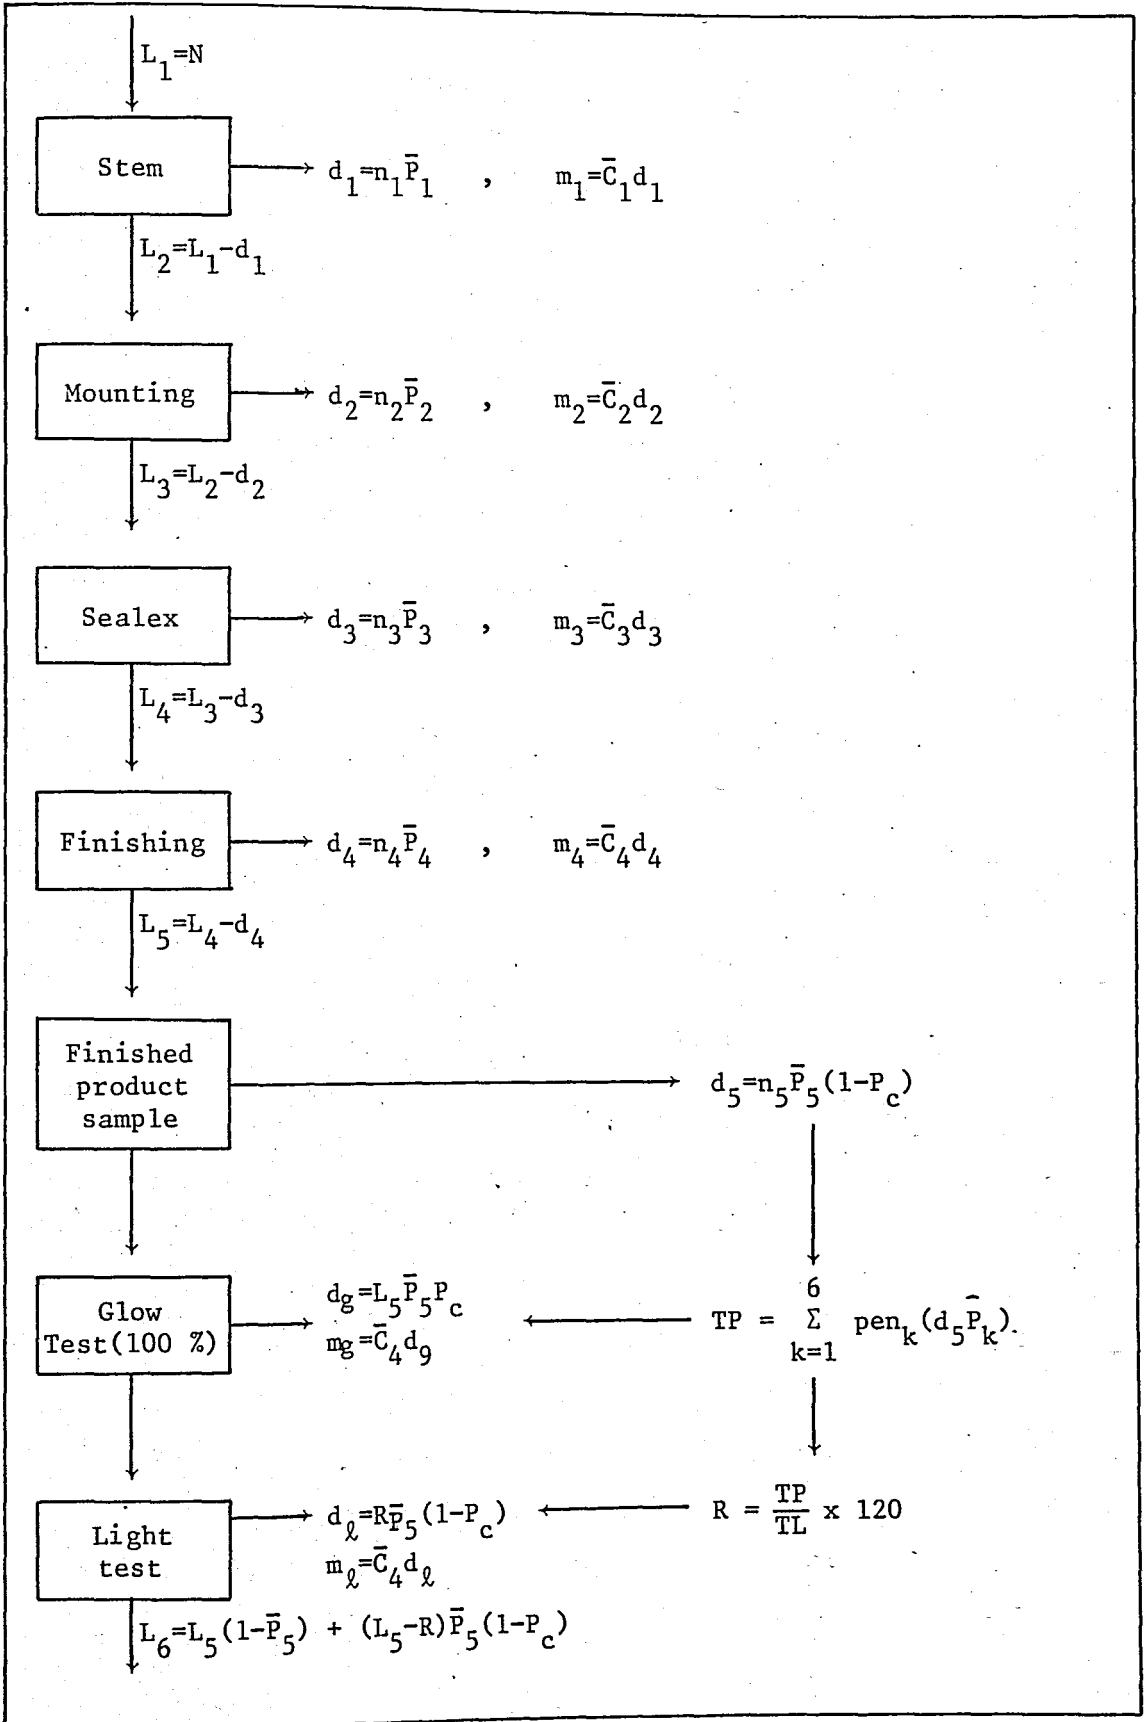

FIGURE 3.15- The Model of the Inspection Procedure

The variables on Figure 3-14 are defined below (for a particular machine group):

- N : initial lot size
- L_i : the lot size at the beginning of each production phase, where $L_1 = N$ and L_6 is the final amount of finished product going to stock.
- d_i : number of defectives caught in sample taken in i^{th} production phase.
- d_g : number of defectives caught at 100 % glow test.
- d_l : number of defectives caught at light test
- n_i : sample size at i^{th} production phase
- \bar{P}_i : probability that a bulb that has passed i^{th} production phase is defective, with

$$\bar{P}_1 = P_1$$

$$\bar{P}_i = ((L_{i-1} - n_{i-1})(1 - \bar{P}_{i-1})P_i + (L_{i-1} - n_{i-1})\bar{P}_i) / L_i$$

for $i=2,3,4$

$$\bar{P}_5 = (L_4 - n_4)\bar{P}_4 / L_5 \quad (\text{for finished product})$$

where, P_i is the probability of a bulb becoming defective during operation i .

- P_c : probability of catching the defective on glow control given that the item is defective.
- P_k : probability that a defect caught in sample light control belongs to seriousness class k .
- pen_k : penalty points assigned to a defect of seriousness class k .
- TP : total penalty points of the defects observed in sample light control.

- PL : penalty limit for rejecting sample boxes during light control.
- R : number of items to take light control, decided as a result of rejections in sample light control.
- \bar{C}_i : average cost of a defective bulb caught at i^{th} production phase. Average cost of a defective finished bulb equals to C_4 .
- m_i : total cost of defectives at i^{th} production phase.

The initial lot size (N) is taken as a random variable distributed uniformly between upper and lower limits for daily production which are set by the decision-maker. So, the limits of the uniform distribution are decision variables.

Other than that, the process average of i^{th} operation, (P_i), is regarded as a normally distributed random variable with mean P_i' and standard deviation, σ_i' . The Central Limit Theorem is used in making this assumption.

The mean, P_i' , and the standard deviation σ_i' are parameters to be estimated by the system. The other parameters are the probability of catching a defective in glow control (P_c), the probability that a defect in light control is from seriousness class k (\bar{P}_k), and the average cost of a defective at each stage of production (\bar{C}_i). All these parameters are estimated using the sample statistics of a sample consisting of the inspection data of last 20 work days.

The decision variables are related to sampling plans and procedures. Each n_i is a decision variable. There are four alternatives in determining the sampling plan at a particular production phase:

1) The Constant Sample Size Plan: A constant number of items are inspected at certain time intervals. This is the current sampling plan used. The constant daily sample size is the decision variable.

2) 100 % Inspection Plan: This is the extreme case of the previous plan where the sample size equals the lot size.

3) CSP-1: A special set of inspection plans, known as Continuous Sampling Plans (CSP), has been introduced for use in continuous production inspection. The earliest CSP, introduced by Dodge in 1943, is referred to as CSP-1. In CSP-1 there are two levels of inspection. 100 % inspection and inspection at a rate of $1/n$ and there is a simple rule to determine when to change between these levels. A producer operating a continuous sampling plan such as CSP-1 may have any or all of three different aims in view(35):

(i) Product screening: The product is to be sorted usually into two grades, an acceptable grade and one which needs to be rejected or rectified.

(ii) Process trouble shooting: The aim is tracing and eliminating the "assignable causes of variation" in product quality.

(iii) Adaptive control: Here the inspection results are to be used to indicate any adjustments needed to the process in order to keep quality up to standard.

The procedure used in CSP-1 sampling plan can be stated as follows:

Inspect every item until i successive items are found free of defects, and then inspect only a fraction f of the units, selecting individual sample units one at a time from

the flow of product, in a manner to assure an unbiased sample. When a defective item is found, revert to 100 % inspection, and continue until i successive items are found free of defects.

The decision variables are, therefore, f and i . Curves giving necessary information for the selection of such a plan for any desired AOQL are given in statistical Quality Control books(36,37).

The average number of items inspected in a run of 100 % inspection is

$$u = (1-q^i)/pq^i \quad (3.1)$$

where $q=(1-p)$ and p is the fraction defective.

The average number of items passed under the sampling procedure before a defect is found equals

$$v = 1/fq \quad (3.2)$$

The average fraction of total produced units inspected in the long run equals

$$AFI = (u+fv)/(u+v)$$

or,

$$AFI = f/(f+q^i(1-f)) \quad (3.3)$$

The derivation can be found in(35).

In the model, (3.3) is used to determine the average daily sample size when the chosen sampling plan is CSP-1.

4) No Inspection: The last alternative when determining the sampling plan at a certain location in production is making no inspection there. In this case, the particular sample size is simply taken to be zero.

Coming to the finished product inspection, the decision variables are the sample size expressed as a fraction of the lot size (L_5) and penalty points limit (PL) to be used in decisions of rejecting a sample box in sample light test, to determine the number of units to be taken into light test (R) (See Section 3.1.2).

In addition to these, the decision maker is allowed to treat the mean for the process average (P_1) as a decision variable, although it was previously defined as a parameter estimated by the model. He can do this by editing the results of the parameter estimation phase. This is a quite important feature of the model, giving it the ability of experimenting with technological aspects of the system. Thus, a new class of decisions that the system can deal with is introduced, i.e., using this feature, the decision maker can evaluate the consequences of an engineering project aimed at reducing the process average by some amount.

The performance measures made available to the decision maker in evaluating alternatives are:

(i) The cost of defectives at each stage (m_i)

(ii) The total cost of the alternative, defined as

$$M = \sum m_i \quad (3.4)$$

(iii) The cost weight of each stage in the inspection procedure, defined as

$$w_i = m_i / M \quad (3.5)$$

(iv) The percent defective at each stage of production, \bar{P}_i

(v) The average outgoing quality, defined as

$$AOQ = (L_6 - R)\bar{P}_5(1 - P_c)/L_6 \quad (3.6)$$

(vi) The material efficiency, defined as

$$E = L_6 / L_1 \quad (3.7)$$

Performance reports for Inspection Plans display all these measures defined above, next to the particular trial inspection plan as defined by the decision-maker.

3.3. USER'S VIEW OF QCDSS THROUGH A SCENARIO

In this section, QCDSS will be demonstrated through a short scenario to make it clear the way it will be used to discover a problem. The figures given on tables are realistic but hypothetical.

By the end of the first month, the Quality Control Manager decides to make an analysis of the quality performance.

He enters the Failure Analysis Module in the Main Menu of QCDSS. He decides to start the Failure Analysis at the Control Station level which is the fourth alternative on the Analysis Level Menu. He specifies the control station as Mount Control which is the first control station in the current inspection plan.

From the Table Menu for Control Station Level (See Appendix A) he initially chooses the first table type, that is Machine Groups compared for the Overall Period. He determines the analysis period as 02/01/1984-27/01/1984

which correspond to the first 20 workdays of the year.

The table appears on screen and he begins to examine it (See Table 3.2). On this table, results for 2 shifts of Machine A and 2 shifts of machine B can be compared. It is seen that second shift of machine A(A/2) displays poor performance, with a considerably higher defective percentage and cost weight when compared to the others.

After making this observation, the user wishes to see the same table, this time for the second control station, on the Finishing Control (See Table 3.3).

Here again A/2 is the worst and the cost figure is even larger for this control station.

The QC Manager wants to get further information about this problem and he decides to examine the situation on time axis. So, he resorts to the third table type on the same analysis level, that is Time-Series Comparison of Machine Groups. First, he demands to see the weekly defective percentages (See Table 3.4).

He makes an important observation on this table. While the defective percentages are about 11 % and seems to be relatively stable for the last 3 weeks for the first shift of machine A (A/1), the defective percentages for the second shift (A/2) are considerably greater (about 15 % on the average) and they tend to increase. When the manager changes the contents of the table for the cost weights, he observes that the cost weight for A/2 is the largest for all weeks (See Table 3.5).

The QC manager begins to theorize on the cause of this problem. Since the machines are the same, this difference on

TABLE 3.5. Time-series table with respect to Machine Groups for weekly cost weights in Finishing Control

the two shifts can result from either the material or operator error. The use of different material seems to be a far possibility, but the manager decides to learn about that.

Before setting out for action, the manager searches for some further clues. He changes the analysis level to (control station/machine group), the sixth choice on the menu, and thus concentrates on A/2.

On this level he examines the table for the First Five Defects (See Table 3.6). The five defective types listed on this table, account for about 62 % of the total quality cost on Finishing Control of machine A/2, and their cost weights are not too much different from each other. In other words, the defects seem to be equally distributed. This observation strengthens the managers hypothesis that the operator is responsible for the situation. Furthermore, observing that the majority of defects are produced in sealex operation, the QC manager now knows where to look at first when judging the operators.

Thus, developing a hypothesis for the cause of the high defective percentage on the second shift of A/2, which is the most important problem for the time being, the QC manager goes to production to find out whether he is right in his hypothesis.

Let's say that, as he has expected, the material used on the two shifts were the same and that the operator on sealex machine was found responsible of the situation. Assume that some corrective action was taken and after two weeks the QC manager once again applies to QCDSS to evaluate the results.

He examines the Time-Series Table for Machine Groups for the last 6 weeks (See Table 3.7). He observes that the precaution has been effective-the defective percentage falling from 15.38 % to 12.92 % on the 5th week and to

B/2	15.11	30.09	22.42	32.72	28.41	56.90	30.94

TABLE 3.8. Time-series Table for cost weights for the last six weeks

9.86 % on the 6th week. While this occurred, the other machines performed relatively stable, except that on B/2 there was a sudden and short-living recovery on the 5th week, parallel to the event of A/2. This seems an interesting point to investigate.

Actually, when looking at the Time-Series Table for the Cost Weights it comes up that now B/2 has gained importance (See Table 3.8).

This simple scenario will be ended here with the conclusion that while deciding where to attack and evaluating results through the use of Failure Analysis module of QCDSS, the decision maker learns much about the behavior of the QC system.

IV. CONCLUSIONS AND EXTENSIONS

In this chapter, the important characteristics of QCDSS will be summarized and some brief remarks on its evaluation will be made. Later on, some possible extensions to the system will be mentioned.

4.1. IMPORTANT CHARACTERISTICS OF QCDSS

The main features inherent in QCDSS can be summarized in a way parallel to the set of capabilities expected from a DSS (See Section 1.2.3):

- (i) It supports decisions which are not so well-defined or clear in the decision-maker's mind. Each chronic problem may require a different solution procedure, i.e. different subsets of data to be searched, different people concerned, different type of suggestions to be made, different judgemental criteria to be considered, etc. Therefore, the decision-makers will have difficulty in defining the solution procedure at the very start, but will find their way out through the use of the QCDSS which will lead them to scientific management approach.
- (ii) The two types of decisions that QCDSS support - changing the inspection plan and launching a quality improvement

project - are at operational and managerial control levels, respectively. Thus, QCDSS helps integration of these two levels. This means that, QCDSS can act as a communication medium between levels of management and diffuses knowledge.

(iii) While changing the inspection plan is an independent decision that the QC manager is responsible of, the launching of a quality improvement project is a pooled interdependent decision resulting from the interaction among several departments. Here again, QCDSS facilitates communication and thus increases the chance of successful implementation.

(iv) QCDSS offers some support for all phases of the decision-making process.

Intelligence phase is supported by the Failure Analysis Model for the identification of the problem. This model also provides some clues for the causes of these problems, but statistical techniques to test the significance of each possible cause is not offered by the available system in this initial version.

The design and choice phases are supported by the "Revision of the Inspection Plan" where a large variety of alternatives can be generated, evaluated and compared.

(v) The menu driven, flexible structure of QCDSS makes it process-independent, allowing the user apply its capabilities in a sequence and form that fits his own cognitive style.

(vi) The ease of use has been one of the main concerns in designing the QCDSS. It does not require the user to have any knowledge on computers.

(vii) The modular approach used in designing the QCDSS makes it highly adaptable to changes, i.e., additions or deletions of submodels are easy and changes in the system can be easily accommodated into the QCDSS by making use of the flexible design of data files.

Thus, when building the QCDSS there has been some consideration for each of the performance objectives a DSS should possess, in general.

Also, QCDSS combines data, model and dialog subsystems, in a manner to achieve an integration which is most appropriate to the problem, the decision-maker's understanding of the problem and the decision environment.

4.2. THE EVALUATION OF QCDSS

The evaluation of a DSS is a difficult task because the cost/benefit analysis approach which deals primarily with those benefits which can be quantified, is not sufficient. Both the "soft" qualitative benefits and the "hard" payoffs should be considered(38).

Qualitative benefits result from investigating more alternatives, doing more sophisticated analysis of alternatives, using better methods of comparing alternatives making quicker decisions and so on. Often it is difficult to identify the added value by the DSS, because it does not occur in a routine basis. Measuring added value is complicated by the difficulty of linking increased profits or other monetary measures to a change in the decision-making process(24).

Some possible measures that can be used in evaluating the impact of DSS are listed below. These are divided into four categories(9):

(i) Productivity Measures - These are used to evaluate the impact of DSS on decisions:

- Time to reach a decision
- Cost of making a decision
- Results of the decision
- Cost of implementing the decision

(ii) Process Measures - These are used to evaluate the impact of DSS on decision making:

- Number of alternatives examined
- Number of analyses done
- Number of participants in the decision making
- Time horizon of the decision
- Amount of data used
- Time spent in each phase of decision making

(iii) Perception Measures - These are used to evaluate the impact of DSS on decision makers:

- Control of the decision making process
- Usefulness of the DSS
- Ease of use
- Understanding of the problem
- Ease of "selling" the decision
- Conviction that the decision is correct.

(iv) Product Measures - These are used to evaluate the technical merits of the DSS:

- Response time
- Availability
- Mean time to failure
- Development costs

- Operating costs
- Maintenance costs
- Education costs
- Data acquisition costs.

A valid evaluation of QCDSS can be made only after its implementation. Nevertheless, a few points can be stated here:

(i) At each phase of decision a large number of alternatives are offered to the user and a large amount of data is made available to him. These characteristics are expected to improve the quality of decisions.

(ii) The control of the decision-making process is at the user, he can do as many number of experiments as he wishes to. These features are hoped to help the user to improve his understanding of the problem.

(iii) The system is easy to use, there are no pre-requisites for the user. Furthermore possibility of error is tried to be reduced to minimum.

(iv) The operating cost of QCDSS will be insignificant because it imposes no additional data and personnel requirements.

4.3. POSSIBLE EXTENSIONS TO QCDSS

A DSS is said to be never complete. QCDSS, not implemented yet, is at the initial iteration of its iterative design procedure. So, many possible extensions to it can be thought of. A few of them will be mentioned here.

A model to support the cause investigation step of the intelligence phase may be the next thing to add to QCDSS.

This will be a statistical model, containing ANOVA type of techniques to be used in determining the significance of various possible causes of the problem such as machines, shifts or material.

A second extension may be the embedding of a control chart application into the data base management software. This will increase the control and knowledge on the existing system and thus increase intelligence capabilities of QCDSS. Such an extension will not require much work since the relevant data is already available.

Another extension can be adding graphical capabilities to QCDSS. Thus the dialog subsystem will be enriched and the user's perception of the system will be increased.

Lastly, by increasing the report generating capability of QCDSS, its data base can be used with management information purposes, in obtaining regular reports to various departments (See Section 2.4). These multi-purpose usage opportunities will increase the benefits obtained from the system, making it more cost effective.

APPENDIX A

TABLES AVAILABLE IN FAILURE ANALYSIS MODULE

Here, available table types in all six analysis levels of Failure Analysis will be presented. On each table type there are a number of items that should be specified by the user and these are indicated by the letters "u.s." corresponding to "user specified".

ANALYSIS LEVEL I: GENERAL

a) TABLE 1: For the Overall Period

Displays a summary of information for the overall of a period specified by the decision-maker where the quality performance of product groups can be compared to each other.

ANALYSIS LEVEL : GENERAL

PERIOD : u.s. (i.e. 01/01/84-31/03/84)

<u>Product Group</u>	<u>Produced Amount</u>	<u>Inspected Amount</u>	<u>Total Defectives</u>	<u>Scrap</u>	<u>Rework</u>	<u>Cost (TL)</u>	<u>Defective Perc. (%)</u>	<u>Cost Weight %</u>
Incand	---	---						
Flour.	---							
Mer.Vap.								

b) TABLE 2: Time-Series

The performance on product-groups can be examined on time scale. The period chosen by the user is divided into intervals of length specified by him and either defective percentages or the cost weights are displayed. Also, the averages of all intervals are given.

ANALYSIS LEVEL : GENERAL

PERIOD : u.s.

INTERVAL LENGTH: u.s. (week, month or quarter)

CONTENT : u.s. (defective percentage or cost weight)

<u>Product Group</u>	<u>Interval 1</u>	<u>Interval 2</u>	<u>Average</u>
Incand.				
Flour.				
Mer.Vap.				

ANALYSIS LEVEL II: PRODUCT GROUP

a) TABLE 1: For the Overall Period

All information for the lamp types belonging to the product group the user specifies is summarized for the given period. The table may be designed such that it includes all machine groups or only specified one(s).

PRODUCT GROUP : u.s. (i.e. Incandescent)

PERIOD : u.s.

MACHINE GROUP : u.s. (i.e. all)

Lamp Type	Produced Amount	Inspected Amount	Total Defectives	Scrap	Rework	Cost(Π)	Defective Perc. (%)	Cost Weight(%)
15 W	---	---						
25 W	---							
⋮								
TOTAL	---							

b) TABLE 2: Time-Series

The table displays the desired percentage type in all intervals of the chosen period for each lamp type belonging to the specified product group.

PRODUCT GROUP : u.s.

PERIOD : u.s.

INTERVAL LENGTH: u.s.

CONTENT : u.s.

MACHINE GROUP : u.s. (i.e. Machine A)

TOTAL PRODUCTION =

INSPECTED AMOUNT =

Lamp Type	Interval 1	Interval 2	Average
15 W				
25 W				
⋮				

ANALYSIS LEVEL III: LAMP TYPE

a) TABLE 1: For the Overall Period

Shows the quality performance of a particular lamp type in a particular product group at each of the control stations, in a certain period. The table may aggregate all machine groups or it may be designed for specific machine groups only.

LAMP TYPE : u.s. (i.e., Incandescent 15 W)
 PERIOD : u.s.
 MACHINE GROUP : u.s.

<u>Control Station</u>	<u>Produced Amount</u>	<u>Inspected Amount</u>	<u>Total Defectives</u>	<u>Scrap</u>	<u>Rework</u>	<u>Cost (TL)</u>	<u>Defective Perc. (%)</u>	<u>Cost Weight(%)</u>
Mounting	---	---						
Finishing	---							

b) TABLE 2: Time-Series

Displays the changes in the quality performance of a particular lamp type in time, at each of the control stations in terms of defective percentage or cost weight.

LAMP TYPE : u.s.
 PERIOD : u.s.
 INTERVAL LENGTH : u.s.
 CONTENT : u.s.
 MACHINE GROUP : u.s.

TOTAL PRODUCTION =
 INSPECTED AMOUNT =

<u>Control Station</u>	<u>Interval 1</u>	<u>Interval 2</u>	<u>Average</u>
Mounting				
Finishing				
⋮				

ANALYSIS LEVEL IV: CONTROL STATION

a) TABLE 1A: For The Overall Period-With Respect To Machine Group

Displays the aggregate information for a specific control station with respect to the machine groups.

PRODUCT GROUP : u.s.
 CONTROL STATION : u.s. (i.e. mounting control)
 PERIOD : u.s.

<u>Machine Group</u>	<u>Produced Amount</u>	<u>Inspected Amount</u>	<u>Total Defectives</u>	<u>Scrap</u>	<u>Rework</u>	<u>Cost (TL)</u>	<u>Defective Perc. (%)</u>	<u>Cost Weight(%)</u>
A	---	---						
B	---							
:								
TOTAL	---							

b) TABLE 1B: For The Overall Period-With Respect To Lamp Type

Displays the aggregate information in the chosen period for a specific control station with respect to the lamp types controlled at that station. Machine group can be specified if desired.

PRODUCT GROUP : u.s.
 CONTROL STATION : u.s.
 PERIOD : u.s.
 MACHINE GROUP : u.s.

<u>Lamp Type</u>	<u>Produced Amount</u>	<u>Inspected Amount</u>	<u>Total Defectives</u>	<u>Scrap</u>	<u>Rework</u>	<u>Cost (TL)</u>	<u>Defective Perc. (%)</u>	<u>Cost Weight(%)</u>
15 W	---	---						
25 W	---							
:								
TOTAL	---							

c) TABLE 2A: Time-Series-With Respect To Machine Group

For a particular control station, displays the chosen percentage type in all intervals of the specified period for each of the machine groups.

PRODUCT GROUP : u.s.
 CONTROL STATION : u.s.
 PERIOD : u.s.
 INTERVAL LENGTH : u.s. TOTAL PRODUCTION =
 CONTENT : u.s. INSPECTED AMOUNT =

<u>Machine Group</u>	<u>Interval 1</u>	<u>Interval 2</u>	<u>Average</u>
A	----	----		
B	----			
:				

d) TABLE 2B: Time-Series-With Respect to Lamp Type

For a particular control station, displays the chosen percentage type in all intervals of the specified period for each of the lamp types controlled at that station.

PRODUCT GROUP : u.s.
 CONTROL STATION : u.s.
 PERIOD : u.s.
 INTERVAL LENGTH : u.s.
 CONTENT : u.s. TOTAL PRODUCTION =
 MACHINE GROUP : u.s. INSPECTED AMOUNT =

<u>Lamp Type</u>	<u>Interval 1</u>	<u>Interval 2</u>	<u>Average</u>
15 W				
25 W				
:				

ANALYSIS LEVEL V: CONTROL STATION/LAMP TYPE

a) TABLE 1: Time-Series

For each interval in the specified period information on the specified control station/lamp type combination is displayed. In the "First Three Defects" section, the defective percentages for the first three defects whose cost weights in the overall period are largest, are given.

PRODUCT GROUP : u.s.
 CONTROL STATION : u.s.
 LAMP TYPE : u.s.
 MACHINE GROUP : u.s. (i.e., all or Machine A, etc.)
 PERIOD : u.s.
 INTERVAL LENGTH : u.s. TOTAL PRODUCTION = ---

<u>Interval</u>	<u>Inspected Amount</u>	<u>Total Defectives</u>	<u>Defective Perc. (%)</u>	<u>Cost (TL)</u>	<u>- THE FIRST THREE DEFECTS -</u>		
					<u>Code 1</u>	<u>Code 2</u>	<u>Code 3</u>
1st Week	---	---					
2nd Week	---						
⋮							
TOTAL	---						

b) TABLE 2: For First Five Defects

Detailed information on the first five defects whose cost weights are the largest among all those observed in the specified period are displayed for a particular control station/lamp type combination. "Related Operation" gives the origin of the defect.

PRODUCT GROUP : u.s.
 CONTROL STATION : u.s.
 LAMP TYPE : u.s.
 MACHINE GROUP : u.s. TOTAL PRODUCTION = ---
 PERIOD : u.s. INSPECTED AMOUNT = ---

<u>Defect Code</u>	<u>Defect Description</u>	<u>Related Operation</u>	<u>Quantity</u>	<u>Defective Perc. (%)</u>	<u>Cost Weight (%)</u>	<u>Cumulative Weight (%)</u>
---	---	---				
---	---					

ANALYSIS LEVEL VI: CONTROL STATION/MACHINE GROUP

a) TABLE 1: Time-Series

For each interval in the specified period information on the specified control station/machine group combination is displayed. In the "The First Three Defects" section, the defective percentages for the first three defects whose cost weights are the largest in the overall period are given.

PRODUCT GROUP : u.s.
 CONTROL STATION : u.s.
 MACHINE GROUP : u.s.
 PERIOD : u.s.
 INTERVAL LENGTH : u.s. TOTAL PRODUCTION = ---

<u>Interval</u>	<u>Inspected Amount</u>	<u>Total Defectives</u>	<u>Defective Perc. (%)</u>	<u>Cost (TL)</u>	<u>- THE FIRST THREE DEFECTS -</u>		
					<u>Code 1</u>	<u>Code 2</u>	<u>Code 3</u>
---	---	---					
---	---						
<u>TOTAL</u>	---						

b) TABLE 2: For First Five Defects

Detailed information on the first five defects whose cost weights are the largest among all those observed in the specified period are displayed for a particular control station/machine group combination. "Related Operation" gives the origin of the defect.

PRODUCT GROUP : u.s.
 CONTROL STATION : u.s.
 MACHINE GROUP : u.s. TOTAL PRODUCTION = ---
 PERIOD : u.s. INSPECTED AMOUNT = ---

<u>Defect Code</u>	<u>Defect Description</u>	<u>Related Operation</u>	<u>Quantity</u>	<u>Cost (TL)</u>	<u>Defective Perc. (%)</u>	<u>Cost Weight (%)</u>	<u>Cumulative Weight (%)</u>
---	---	---					
---	---						

APPENDIX B
NOTES ON PROGRAMMING ASPECTS

QCDSS has been designed on Commodore CBM 8065 micro computer with 5 1/4 - inch dual floppy disk drives CBM Model 8050 and bi-directional printer MPP-1361.

Commodore BASIC Version 4.0 has been used as the programming language and QCDSS has been programmed on 32 K CBM BASIC text area as a number of modules chained to each other through the Main Menu. The selected module is automatically loaded and run by the program.

Of these modules "Failure Analysis", "Revision of the Inspection Plan" and "Data Input" are documented in Appendices C, D and E, respectively.

APPENDIX C
LISTING OF THE COMPUTER PROGRAM FOR
FAILURE ANALYSIS MODULE

Here, the main body of the Failure Analysis Module and the subprograms corresponding to Control Station and Control Station/Machine Group levels of analysis are being documented.
